Now for the old open secret, if such it may be called Now for time out open secret, it men to many to constitute if when the brakes fall to operate, the reverse leves is thrown clear over, with the throttle closed of course, the wheels will continue to revolve in the forward direction, but even then they excet some retarding force; then if a small amount of steam be admitted. force; then if a small amount of steam be admitted the retarding force will become greater, yet the wheels will continue to revolve in the forward direction, and so long as they continue to revolve in that direction, with the above conditions, two are holding back on the train. Of course, if enough steam is admitted to reverse the motion of the wheels, then practically no force is expected, but an engineer who known his business. force is exercic; but an engineer who knows his business and his engine can gage the steam so that he will get very nearly its ultimate tractive power to hold back on the train. Of course, sanding the track will help also, as it gives greater cohesion and enables him to use even more s cam without the wheels slipping or turning backward.

I dislike to take part in a discussion of this nature in any periodical, but when I see such mistaken ideas d as was done by your correspondents, and in a paper which I consider an authority on technical matters, I cannot refrain. I am gratified that the Editor in his remarks on this subject on July 5th did not coincide with the correspondents, but my explanation above more clearly explains the value of reversing when the brakes fail to work.

C. E. W.

### A Railroad Adopts the Automatic Stop.

To the Editor of the SCIENTIFIC AMERICAN;

To the Editor of the SCIENTIFIC ARBRICAN; Had the Jones subtrantic sol signal and train control system, as installed and operating on the Maryland & Pennsylvania Hallroad out of Baltimore, been installed on the New Havon road, the fearful rear-send collision caused by the fog preventing the engineer from seeing the signal, would not have occurred.

The Jones system is the electrical closed-chronic system, in the control of the signal would not have the signal when the signal would not have the signal would not have been supported by the signal would not be supported by the si

the signal, would not have occurred. The Jones system is a clostrical closed-circuit systems, operating signals and the application of the sir in the engine actorization, and an arranged that a train moves within a sone of protection, both front and rear, against poin switches, broken rain, received sign hand-on collisions. It has been tested through sizet and move and works more perfectly than the humans arind. The teste is divided into blocks, and as a train approaches a block which is occupated, or whire; there is an open switch, that unginose is signalled by a warning hell in size and it is not because being in the does not control the stein, and attempts to enter the block, or within a cortain distance of the charge being. In it brains are not not foundation. When the block is closer he gets a signal its process, it also provided the oughest tailing a consequent above a perfect state the control of the stein and the state of the internal before a substantial case. It is processed the agreement allows the engineer tailing a consequent above a perfect state the control of the state of the state of the latter of the state of the

d by the Interstate Commerce Commission and the Railway Signal Association, and can be installed in conjunction with the present signal

be installed in conjunction with the present signal systems as comparatively small cost.

The New Haven road offered a prise of \$10,000 for a system that would prevent rear-end collisions, to be tried on their road. If successful, however, they are to be allowed to use it over all their systems for nothing. The Joage Company would not onter into such a on-sided proposition, but submitted a counter-proposition, sees proposition, but summitted a counter-proposition, as follows: The Jones Company to equip a portion of the New Haven road with their system at their own expense, the New Haven road to operate it an agreed length of time under their own management. If satisfied the counter their own management. factory, the railroad company to pay a predetermined es; if not satisfactory, the installation to be removed

prior; if not satisfactory, the installation to be removed without any expense to the New Haven rolland. An identical preposition was made to the Maryland & Pennsylvania Ralibrad running out of Ralimore. After testing it for a period of eight months and having it passed on by some of the best signal engineers in the souther, they adopted the system, as per the following

Baltimore, July 9th, 1913.

Mr. Calvin W. Hendrick, President the Jones Safety Train Control System Co.

Baltimore, Md.
Dear Sir: We have r

own nir: We have recently increased our passenger train service between Baltimore and Belair, and after the first of September the freight train service will be increased also, and there will be a considerable movement on the tracks hetwood Date.

As your automatic cab signal and train stop has m all tests placed on same by us during eight months's operation under regular train service, we have decided to adopt the system on our road. You will therefore under the provisions of the contract we have with you regarding extensions, and extend your system on our road to Towson, Md., including the north switch of siding at Towson. In doing the work, please include red suggestions made by Mr. Scott in his examination of the system now in use,

### Yours truly, (Signed) W. B. BROOKS, Vice-President.

We are now the only automatic cab signal and train We are now the only automate can signal and train control system on a closed-circuit principle that is in daily operation and has a bona fide contract with a rail-road. The closed-circuit feature has been one of the most difficult requirements of the Interstate Com-merce Commission to meet. This feature gives prompt notice to the engineer should any part of the apparatus

Electricity has become a dependable factor, and the automatic electrical control of train movements is bound to come in the near future, as the present controi of the trains is costing too great a sum in lives and property. Such appalling accidents as have been happening in the past two years, together with the one that has just happened, are causing a profound impression in Washington that something is radically wrong, and automatic stops to check the engineer have

As the roads have been claiming that there is such automatic train stop in existence, I thought this an opportune time to let you know the above facts.

Calvin W. Hendrick, President.

Baltimore, Md.

(It is not the practice of the SCIENTIFIC AMERICAN to publish letters of this character; but we feel that the to purchan returns on the character; but we reset that the facts given above, showing that a railroad, after making a lengthy test, has found an automatic stop that is so satisfactory as to warrant its installation, under con-tract, are so timely and significant, that we publish this latter in full.—EDITON.

### Rewarding the Inventor

To the Editor of the SCIENTIFIC AMERICAN: It is generally conceded, I believe, that the inventor has done more to assure the mechanical supromacy of America than any other, although it is likewise popularly believed that he rarely gets the reward should be his.

should be his.

That he is a prolific species is shown by the eight hundred odd patents which are issued each weak by the United States Fatent Office. Not that there are eight hundred money-making inventions patented in America overy weak. The inventors sees mort in the baby of his brain whether practical or not. He has get to be an optimist, A possimist never would invent anything, because he would stark with the idea that the thing sould not be done anyhow.

The inventor in his enthissiana, and the newness of his idea can see it only in a favorable light. Cold facts do not distart him. Se, he goes hillstey alseed and is not at all surprised when he succoded, though everyone eight.

And this is as it should be; for gold facts ought not

unduly to discourage the inventor, nor should ridicule justify him in the abandonment of a revolutionary idea. That a thing has been done differently heretofore, is no reason why a new principle may not be a better The expert is more likely to be wrong than right when it comes to a new pher omenon.

This leads one naturally to the discovery of a neculiar condition, that is, that persons or firms who should do so, rarely buy really big inventions. They go plodding along selling the old device until one day they are shocked to find that the public has forgotten the old love and taken up the new. In the light of past experience, it would seem that they should look excefully into any new and startling invention, if for no

other reason than as a means of self-defense.

It is historical that the telephone was first offered to the telegraph people, who refused to see any merit in the "toy." It is also historical that the telegraph er bought up by the telephone company. disk talking machine was brought to the attention of a musical instrument company, who in rejecting it of a musical instrument company, who in rejecting it said that they were already marketing an instrument which had real merit as a means of enterta The musical instrument referred to has dropped out of , while the disk talking machine speaks for itself in millions of homes to-day.

But there are inventions and inventions; some are improvements of existing devices, meritorious because they enable one to do a thing easier, or in a more simple manner perhaps. Of this kind, the great bulk of inventions are made up. There are other inventions which are revolutionary, which upset the established method of doing things, or which attain a new object heretofore unattainable.

And just here may I cite as a curious fact, that the revolutionary kind, there have been born in the ten-mile square of the District of Columbia, more startling inventions than in any other equal territory in the world. To believe it one has but to think of ti telegraph, the telephone, the electric railway, ti electric light, both the talking machines, the motion picture machine as used to-day, both the type-casting picture machine as used to-day, both the type-casting machines, etc., the bistorical accuracy of which is so strikingly attested by the exhibits in the National Museum. To be sure, newspaper publicity has in some instances placed the invention elsewhore, but this does not disturb the facts in the case, but only points to the carelessness with which loose statements are sometimes accredited the weight of facts.

Pure invention and scientific investigation so blend into each other that the line of separation is not a marked one. The mind which conceives the one, is the mind which most easily attains in the other field. The mind which conceives the one, Both men are plodders, and take satisfaction more in the attainment of the end, the addition they contribute the attainment of the end, the addition they contribute to the sum total of human knowledge, than in the financial reward. And perhaps this is the real basis for the popular belief that the inventor rarely reaps adequate reward for what he contributes to the comforts and convenience of his fellow men

The inventor, the scientist, and the artist, are each popularly pictured as a personality obsessed by a single idea, and incidentally that single idea is not financial reward. He has a satisfying ideal, the pursuit of which, reward. He has a satisfying ideal, the pursuit of which, however, not only keeps him a poor man, but often works a hardelilip on those near and 'dear to him. And that is the real pity of it. The necessity, therefore, of turning saids to some more or less renumerative employment pushes his ideal more and more into the background, until finally districts and more more or considering the control of the control

This situation, namely, the necessity of carning daily read for himself and his, has wrecked more worthy inventions, with the attendant loss of the development funds, than any other single cause. If, however, the financial backers of the invention had the farsightedmeet to finance the inventor's family, more inventions would reach their fruition, especially revolutionary ones, the results of long-drawn-out study and experi-

I know that this statement will be seized upon by alleged inventors as a means to the end of living off their fellows. But in what very few instances this their relicions. But in what very low instances this may be so, perhaps it is only turning the tables, for, on the other hand, the inventor is notoriously the victim of the man who furnishes him money.

The real inventor, he of the scientific idea, is almost always a worthy man. He follows a high ideal and

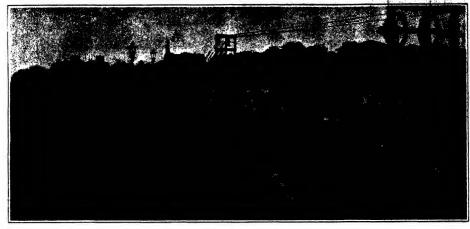

ot very well be wholly had. Being honest limiself slieves others honest, and becomes, therefore, the easy victim of the unprincipled promoter, and this is

So in conclusion, if this preschment should strengthen termination of some discouraged inventor, or aid in securing honest financial backing for his applicaadd in securing honest financial backing for his applica-tion, and the development of his great idea, it will be a further refutation of the belief that he is the legiti-mate prey of the heartless "moneyed man" and the equally unscruptulous lawyer. C. Francis Jenkins. Weshington, D. C.

### Sawing a Bridge With a Wire

An Old Idea Revived and Improved

By Jacques Boyer

How the old Pont Neuf was sawn apart.

siteration strengtonese the bridge by diminishing the load borne by the arches and plers.

Now the old bridge has been subjected to a remarksible engineering operation for the purpose of forming, in its solid mass and throughout its entire length, a conduit for elsectric cables connecting certain transway lines on one side of the Seine with a powerhouse recently erected on the other side. For this purpose it was necessary to gut a tracefu more than 4 feet with and nearly 7½ feet deep, leaving a thickness of only 20 inches over tite tops of the arches. In the shorter

arm of the bridge the work presented no difficulty, as the mass consisted of rubble, which yielded rendily to the pick and the pneumatic hammer In the longer arm, extending for a length of 550 feet from the statue of Henri IV. to the right bank of the Seine, a solid mass of asidar, cemented to-gether with concrete containing flint pebbles was encountered. As this mass could not be atneked with explosive or with wedges without endangering the stability of the bridge, the contractor decided to saw it longitudinally with a helicordial wire

Before entering into the details of the opernations required for the solution of this peculiar problem it should be observed that the idea of sawing stone with an endless wire and a pulverised abrasive p more than fifty years old. Various applications of this process are mentioned in a patent granted to Eugène Chevalier in 1854.

Chevaler claims "the employment, as a saving tool, of one or more metal wires, cords or chains, acting with a continuous or alternating rotary motion, and sufficiently flexible to attack all sides of the block of stone simultaneously." This interesting process, however, was forgotten until 1884, when it was revived by Paulin (say, with the aid of a Belgian contractor, M. Michel Thomar. Four years later, Thomar improved the process by introducing ball-bearing wheels, by which the cable can be guided in any direction, and boring tools of great diameter for the sinking of shafts for the purpose of separating the sawn blocks in the

The process still presented a serious practical inconvenience—the difficulty of repairing the wire or cable in case of rupture. Joints made by soldering or brasiles in the most careful manner frequently gave way. At last a workman conceived the idea of untwisting the state of the brasiles of the process o

ent lengthe and uniting them by a spitce four yards iong. This device proved successful, and the supporment of the selectionals wire become general in searble and granite quarries, as this method of separating the blucks combine rapidity with economy, avoids the employment of explosives, and, above all, dispenses with the long and everity operation of cutting trends through the rock. The recent operation on the Post Neuf, however, is the only instance known to the writer of the employment of the beliefolds wire for sawing a bridge.

The work on the Post Neuf was divided into three

The work on the Post Near was divided into three section, of which two were 164 feet long and the third was 223 feet long. Four parallel cuts, from 7½ to 8 feet deep, were made in such section by two sets of apparatus working simultaneously. The longitudinal profile of the work was carefully regulated in order to avoid cutting the extrados of the supporting arches.

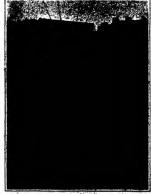

In front of the statue of Henri IV, was erected a wooden senfolding 10 feet high and 26 feet long, which supported a number of wheeled flat cars to which the sawing cables were attached. Each car carried an 18

> horse-power electric motor, a speed reducing shaft and the shaft of the wheel which moved the cable. Constant and uniform tension of the cable was assured by cast from weights suspended from an auxiliary cable attached to the car.

Retwent the sections wells were sunk to the depth of the cutting to be made. In each well were mounted two from poster which carried at their tops guide wheels for the sawing wires. From these wheels for the sawing wires witch descended into the well as the work progressed, and which could be raised by measure of hand-winches. The wire same of hand-winches wire well as the work well as the work was perfectly the same with th

Pegoud demonstrating how the parachute opens clear of the machine.

### Recent Aviation Events Parachule Leap from an Aeroplane

HAT the parachute may become a fac tor as a life-saving device for aviators

Pegoud, who has startled his spectators a number of times by his feats of daring while in the air. Pegoud's experiment consisted of leaving from his manufactured. sisted of leaping from his monoplane descending slowly and safely to the ground by means of a specially construct mrachute, the invention of M. Bo

The experiment was considered ex-The experiment was considered ex-tremely hazardous, and it is stated that Pegoud had a long altercation with the police authorities before he was allowed to attempt the demonstration. The ac-companying reproduced photographs alpo-tic sethod of attacking the parachute to the seronispe. The parachute is contained in a folding sheath attached to the upper part of the fuselage, and the ropes are fixed around the aviator's body. In case of an accident or when the pilot is ready to abandon the machine, he presses a lever which causes the sheath containing the parachute to open, thus allowing the wind to catch the folds of the parachute. As the large umbrells-like structure up olds and inflates itself it rises and lifts the aviator away from the machine with it, thus leaving the plane to its fate, while the fillot descends unfelv.

On the day of the experiment Pegoud ed in a strong wind to a height of

about 900 feet and pressed the lever which released the para-clute. The machine began to descend swiftly and the specta-tors were filled with apprehension; but almost immediately the outline of the parachute revealed itself and the aviator was lifted clear of the machine, dropping slowly and safely to the ground. The aeropiane, left without a pilot, was, of course, completely wrecked when it struck the earth.

course, completely wrecked when it atruck the earth. Pegoud is the aviator who is reported as having recently accomplished the daring feat of flying an aeroplane upside down and again righting the machine and descending safely without damage to the aeroplane or to himself. The machine which Pagound uses in all of his flights is a Bierlot monoplane, fitted with a 50 hone-power Gaoms motor.

A New French Water Glider.
A hydroplane of novel construction has rece maneuvering on the Seine near Paris, driven by M. Teilier, who designed and built the machine. Teilier is a French zero-plane enthusiast who has been engrossed for some time in the study of air-propelled water machines, and has perfected the glider which is illustrated

berewith. This muchine has a typical aeroplane fuselage mounted on three boat-like sows, and is steered by means of a hand-wheel connected with the rudder. In front of connected with the rudger. In front or the driver's seat is an extra seat for a passenger. The hydropiane is driven by a four-cylinder, 50 horse-power Daigner automobile motor, which is connected automobile motor, which is connected with the propoler shaft by a climit. The motor is of the water-cooled type, and is supplied with cooling water. Jon. Sive long vertical radiators placed above the motor at the extreme sud of the France. Wrecked monoplane, which fell to earth after Pegond's parachute leap

wings faces.

of 70 kilometers, or about 435 miles per New Dunne Aeroplane May Solve Sta-bility Problem.

Much interest has been aroused to the world of avlation over the recent series of successful flights of Lieut. J. W. Dunne and Jules Fellx in the new Dunne aero-plane, which seems to prove the contention that stability in air muchlus has at last been realized. The principles upon which the Dunne machine is constructed are simplicity, stability and safety, and if the designer's predictions are realized it is probable that within three or four years the art of flying will be well on the road to perfection, and that with the adoption of the stable aeropiane, flying

will be as safe as automobiling
Although the principle of the Dunne
machine is not entirely new, the V type of wing having been used in gliders as early as 1906, its application to the power plane is an improvement it was chiefly through his experiments with models that the inventor was lead to design his pres ent machine. The principal feature which first attracts the attention is the V shape of the wings with the point at the forward end of the machine. Since the two wings or planes are complete in themselves, being provided with warping extremities, the front elevator and the tall are eliminated. The V-shaped wing is applicable either to

the monoplane or the biplane.

Another feature that is emphasized is the manner in which the front edges of

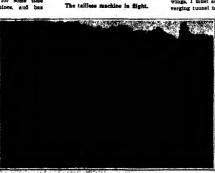

the manner in which the front edges or the wings are turned down so that the plane sections present nearly a cylindrical curve. In a communication to the Aero-nautical Society of Great Britain, read at one of the society's meetings, Lieut. Dunne described his machine, referring par-

meetings, lifett. Dunne described his machine, referring par-ticularly to the construction of the wings, as follows "I give the wings a much more definite arrow form than that of the Zanonia (leaf) type; the tips are rolled down in front instead of rolled up behind, so that we have a concave under surface instead of a concave supper surface in this region; while the outstanding feature of the type is the fact that the whole wing forms the roof-part of a tunnel running backward and outward across the wing, the crown of the tunnel being sloped back at a greater angle than are the wings themselves, and the sides of the tunnel preferably converging toward the rear end. The improvement in efficiency gained this method of construction is very extraordinary; but as wish to confine myself to the safety devices embodied in the wings, I must ask you to take my word for it that this converging tunnel tends to produce a positive pressure under the

negative wing-tip, so that for the same of negative pressure on we are able to use a greater negative unale than in the Zanouin type. And it is the geometrical difference between the angle at the tip and the angle at the front of the machine which counts for me

"My attention having been accidentally directed to fluid flow in diverging, converging, and vena-contracta pipes, it occurred to me that wings bulli in such forms would give pressure distributions quite different from the ordinary, and also quite different travels of the center of pressure, and were therefore worthy of investigation But the stability actually obtained with the first model came as an astounding surprise.

stant-angle-of-incidence-machine such as this is, ipso facto, a constant speed machine. For if the speed is accidentally reduced, the machine begins to sink: this ses the angle of incidence; the re-(Concluded on same 222)

NOW SHOW IN THE PROPERTY OF THE PARTY OF THE

#### How Deadly is Railway Travel?

S TATISTICS have an irritating way of disappointing popular beliefs. That the mortality of railway travel in the United States is too high cannot be open to discussion It will be too high so long as it remains nlove zero list the statistics of the subject disprove such common notions as that it is rising, that it is not failing or that it compares terribly with the average

infinity of railway travel elsewhere in the world.

If you take the number of passengers carried and divide it by the number of killed during a year, in this country and in Europe, you will get a comparwhich is very duraging to the American ratiroud. It will show that in this country one passenger in every four million carried is killed, against one in ten or

twelve million in Europe. But that is not a fair comparison. The average distance such passenger is carried is approximately three times greater in this country than in Europe. It is plain that the risk of travel is in proportion to the distance send miles is a thousand times greater than the risk of traveling one mile. Therefore, the only fulr basis of comparison is that of "passenger miles." The "passenger mile' is a term used to express a unit of passenger transportation. it is one passenger carried one mile. For illustration, the number of passengers car ried by American railroads in 1912 was roughly one billion; but the "passenger miles" were thirty-three billions, because the average distance traveled by each pas-

senger was thirty-three miles. One pas-senger traveling thirty-three billion miles or thirty three billion passengers traveling one mile each would make the same number of "passenger miles" as one billion passengers traveling an average of thirty-three

On the Fair Basis.
On the basis of "passenger miles," a comparison of the mortality of travel in the United States and in Europe is much more favorable to the American rail-Il shows that the number of passengers killed per billion of "passenger miles" was 71/2 in Europe and 8 in the United States, during the years of the latest completed statistics, as follows:

Europe, 1910 . U. S., 1912 .	Passenger miles, 73,555,578,571 33,510,073,000	Passengera killed. 554 270	per, billion pas, miles 7.53 8.06	
U. B., 1912	33,510,673,000	270	8.06	

These statistics refer only to passengers. The mortal ity among employees is another matter, in which dif-ference of temperament between the foreign and American employee is an important factor. Also, as is evident, they refer exclusively to deaths of passengers, and statistics of injuries are purposely omitted, for the reason that they are imperfect. Deaths are a definite quantity and the statistics are continuous, so that comparisons are accurate. That is not true of injuries, which night seem to increase for no other reason than that they are more systematically reported as efforts are made to decrease the risks of travel and railroad employment Actually the ratio of injuries to deaths should be fairly constant

### The Improvement Here.

More important than that the rate of mortality in

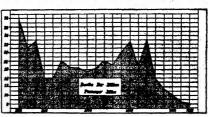

More Important than that the rate of mortality in American railiawy fravel compares less unfavorably with that in Europe than is generally believed is the fact that if is remarkably failling in this country. The "passenaer muleo" (the number of possenaers carried one into reported by all the railways in 102 were 25.010.075.066, and the number of passenaers killed, as reported by the Interstate Commerce Commission. WHE According to the Bureau of Railway News and Statistics, 48 of the killed classed as passengers were in fact em-ployees, so that the net number of passengers killed in 1912 was 270. That is roughly eight passengers to each billion of "passenger miles." In 1892 the numor passenger miles in 1892 the number of passengers killed per billion of "passenger miles" was 28. The fluctuations in the number from 1892 to 1912. inclusive, and the remarkable tendency to doctine, are shown in the chart. The figdecilne, are shown in the chart ares are shown in the table below

To show that rallway travel is not so deadly us it is thought to be is not to say that it is not much more deadly than it ought to be; but certainly the railroads are cutified to the statistical proof of what they have stready done to lower the

That hy the fairest possible statistical comparison the rate of mortality yet is

higher in this country than in Europe lutely prove that the railroads are less by prove that the raincade are less that to protect the lives of possession differences in equipment it is been opean travelers to take the version prican travelers take. Before 2 the differen every passenger is tucked aw scarce every passenger is tucked away in suc ease ment. There is no such thing as a pantly one we to overtake his train. It might be exqued, too the risk of travel increases faster than the fits but that, of course, is an abstraction.—New York

Kaiser Wilhelm Canal Locks the Large

The falling rate of mortality in railway travel.

Wilhelm ship canal has included a reconstruction of the locks on dimensions which entitle them to be called the largest in the world. They are 147.5 feet wide. 1,082.7 feet long and 45 teet deep. The new locks of the Sault Ste. Marie Canal will be considerably longer, 1,200 feet in length over all, but they will be 80 feel in width only as against the 147.6. The Panama Canal locks are 110 feet wide by 1,000 feet in length, with a depth of water of 40 feet.

Engine "Pulling Billy," Wylnes Suffway, 1818. 

ats with a frame mor smooth wheels driven by manu working cranks connected with wheels. The object of this experit wheels. The object of this experimental carriage was to ascortain if a loopmostive engine, having smooth wheels running on smooth rada, could pull anything of a load; for up to that time all loopseiture had toothed wheels running on rack ratin. It is tree that Trevifishel's engines had smooth wheels, but they falled for other

mooth wheals, but they falled for other reasons. The result of lises trials, which were carried on under the supervision of William Hedler, Hackett's "cool riesses," when were so encouraging that early in the year 1813 the frame and wheels were fitted with a cast iron hother and a single steam cylinder d inches in diameter, which drove the wheels through intermediate gearing. After repeated trials with this experimental engine the construction of a new size was decided upon, chiefly because of the defective steaming capacity of the bother. No time was lost, and in the same year Blackett ordered Hedley to rebuild the engine with a new boiler and cylinders. This was done with the senistance of Timothy Hedkowth, who was foreman senific at Wylam othy Hackworth, who was foreman smith at Wylam and a clever mechanic. In fact, at that period blackand a dever mecanic. In net, at that person outco-senths were the only mechanics who worked in iron and practically all the early locomotives were made by them. Hackworth was Stephenson's great rival, and there is no doubt that the "futher or railways" spent his Spandays at Wylam making notes and statches of "roung Billy" and other engines there which were built and partly invented by Hackworth. For this reason Hackworth deserves a more prominent place in motive history than has remerally been assigned to

fling Billy" was finished in May, 1818, and put to work bauling coal wagous on the five miles of track connecting Wylam Colliery with the wharves on the The engine appears to have been successful from art, and it attracted much attention, mingled with opposition from those who were interested in horse It has two vertical steam-jacketed cylinders has dismeter by 36 inches stroke, which by grass b mones casemeter of so incress stroke, which by grass-hopper beams transmit the power downward by con-necting rods to a shaft with cranks set at right angles. This shaft is journaled in the frames, which are of wood, and carries a spur wheel, which, by four other spur wheels, transmits the power to the four driving wheels, each 30 inches in diameter. Steam was die wheels, each 39 inches in diameter. Steam was dis-tributed by short D slide valves worked by a tappet motion. The working steam pressure was 60 pounds per square inch. The boiler is of wrought iron lagged with wood, It has a return — that the furnace is at the same

nue, so that the furnace is at the same and as the chimner, where the fireman attended to his duties, standing in the confer. The engine driver was stationed at the other and of the boiler, where he had the lovers and working parts within early reach. The tender consists of a wooden frame supported on four wheels and carrying a square water tank and coal box. The combined weight of the engine and tender is about tan tons, and engine and tender is about the tone, and its usual performance was to haul fifty long tone at the miles per Bour. The exhaust steam from the crystolers was discharged directly into the chimmer, and the noise these caused arounded so misches control around a misches control around a more control of the modern that legal options was taken opposition that legal options was taken on the subject, but the missuance was subject, but the missuance was subject to the control of the control

#### House Moved in Sections

A N enterprising knows mover in West, The tensary line, Mass, inding it practically impossible to move a three-story dwelling as it stood, silood it straight down through the ridge of the gable, and curted it away in two section. Buch section was about forty feet high. The base, however, was thrity feet in length by twenty in width. The result, of course, was that every moment it threatment be topple over. To obviste this, the brick from the chinneys and the stone from the foundations were leaded upon the first floor for belief.

While the work of alteing was going on, bixons, of course, were required to hold the parts Smuly in position. When the two parts were reseaseabled ten miles away from their original site, the workmen put them together so well that, with a new coat of paint over the whole, no one would over have suspected the remarkable feat that had been achieved.

The house at its old location stood ten feet above the street level. This was the reason that the peculiar method of transporting it had to be resorted to.

### The Eiffel Time Signals

O NE reason why wireless telegraphy seems uncamp is that we have no visible demonstration of the electrical surgings up and down the antenne which generate electro-angentic waves. However, were our eyes constructed to detect the short-wave light beyond the violet portion of the spectrum, we world see the series of a high-powered action acrow with a blush imaliaceocco. This giow, which is invisible to our eyes, is visible to the eye of the samera. The secondparity photograph, taken from the second platform of the Effici Tower and looking up toward the top, showe the ultra-tolet giow abound the antenna. The photograph was taken when the Effici Tower station was taken when the Right Tower station was taken ones to Bellin, and our own Arlington station, and they have proved of great whine to navigators, for hy these they was correct their chramometers and determine their position at we with great accounter.

Announcing the time from the Eiffel Tower. Note the luminescence along the angence.

framework of the hand-driven chair. heavier axie was turned upon his lathe. The rear wheels of the hand-driven chair were too light to carry the heavy machinery of the proposed new chulr, while the els of the smashed motor cycle were too large to fit into the frame of the old clustr. This difficulty held up the work for several days. At last the boy rebuilt the motor cycle wheels, cutting them from 30 to 28 inches. Pneumatic motor cycle tires, the only new things about the whole chair, were then purchased. A gasoline tank was made from a discarded dishpan, and lucased in a box made from the cherry paneling of the headboard of an old bed. Stop cocks from an old gas stove were used to regulate the flow of gasoline. A belt drive being found lande-quate, the boy substituted a chain drive. A band brake on the left side of the mo chair, made from the Iron hoop of an old washtub, works on a drnm cut from sting The same lever that throws a casing the same lever that throws out the clutch applies the brake. The tire of the front wheel is wrapped with a brass window chain to prevent skidding. the rear wheels being equipped with unti-skid tires. A dog chain was at first used on the front wheel but it was musatis-factory. The lever controlling the supply of gas feeding into the carbureter is made from an old file. The cut-off valve is made from a one half inch gas pipe "T," a brass curtain rod and a clock spring. The steering lever is made from a length of gas pipe and the end of a mop handle. The 2% horse-power motor is alr-cooled, the fan being made from an old brass fender, and the blower-case from a the can which at one time held a gallon of apple butter. The blower-case is covof apple butter ered with asbestos to deaden the sound. The boy constructed the entire oiling sys-tem from brass tubing and a little solder A thry bleycle hump to comply with the city ordinance completes the outfit

### Grafting Performed by Nature

IT is common to see a tree or plant grafted by man into another tree or plant of the same class, but of a different But an instance of a tree of one class having been successfully grafted by man into a tree of a wholly different class is certainly most extraordinars. How more of a curlosity, then, would be the sight of a tree of one class grafted by Nature into a tree of another class. And yet such a feat has been accomplished, as witnessed by the accompanying photograph, which shows a cabbage palm—an endogenous tree—solf grafted into an ex-ogenous tree (a tropical evergreen). This photograph was taken in January of this year The tree may be seen about a mlic out of Santa F6, Isle of Pines, West Indies, on the Government road or calzada leading from Santa Fé to Jucaro. 1 11 stands in the front lawn of Mr. L. E. By-crs, an American resident of this isle, which is said to be the "Trensure Island" of R. L. Stevenson. The lower portion of the paim is dead, and can be seen in the photograph close to the young lady. The The upper portion, however, is in perfect condition, and is as smoothly coalesced the body of the exogenous tree as are the latter's own branches, and receives its nourishment from its foster parent. Nature did this wonderful piece of grafting by the method called "hearching," and it probably precedes artificial hearching.

### Remarkable Giant Sea-anemone

THE deep-water reefs off the Islands of southern California, particularly Los Angeles County, are very profile in strange creatures, which are brought up occasionally by fishermen.

the of these odd creatures is shown in the accompanying illustration. It is the glaut of the secamemones, in a land where these animals are glauts in every sense of the word. The amenone is a cound of the coral. The amenone is a cound of the coral polyp; is, in point of fact, a polyp similar to the coral except that it is without the faculty of secretur, line

The anemone here shown is a dweller in water from eight hundred feet to one (Concluded on page 224.)

conscised from page 188 ) sultant between the lift and the negative presents, consequently goes back, which makes the machine dive slightly and thus recover its proper speed. While, if the speed is sceldentally increased, the machine sizes this reduces the argie of in cidence the resultant consequently goes forward which makes the machine ele-

wate and slow down to its proper speed While Lieut. Dunne was carrying on his experiments in England the British War Office could not be induced to take up the promotion of the machine on account of the skepticism which at that time ex isted regarding the future of the heavier than air machine Accordingly Lord Tai libardine, chairman of the Blair Atholl Aeroplane Syndicate of London which was promoting the Dunne machine was forced to negotiate with a French firm for its manufacture hence most of the tests have been made in France

forced to negotiate with a French firm for its manufacture hence most of the tests have been made in France. The most recent demonstrated on the new aeropiane a test which seemed to confirm every contention of the inventor came only recently when Jules Fellx the noted French aviator piloted the Dunne biplane from Eastchurch across the English channel to the French coast during a storm. Upon landing Felix declared that the machine maintained its stability in the high wind to a remarkable degree and predicted that this type of machine will eventually become an important factor in practical seconsulties.

#### The Centenary of a Famous Locomotive

(Concluded from page 280.)

Billy was thus too heavy for the track and it was necessary to carry haif a dozen spare fram-plates on the engine treplace those which might break during the journey Theoretore in 1815 Hedley dacided to rebuild the engine as an eight wheeler and placed each group of sour wheels in a truck frame thus distributing the weight and enabling the engine to round curves with greator case.

About 1890 the Wylam road was relaid with cast from edge ratis of the double-flanged fish belified type with half lap joints supported in chairs spiked to cross sleepers. The gage was 5 feet each rail was four feet long and weighed 30 pounds per yard. The eighte was then rebuilt with four wheels and practically restored to its original form the undier belux removed. It thus worked continuously for about fffy yarr and it was the first size cessful locomotive in the world.

A glance at the illustration will show

A glance at the Hlustration will show that Puffing Billi) beam little rosem blance to the modern locomotive. The explanation is that the locomotive endine is an offshoot of the restionary sugine for the creations of Newcomes and Watt long anti-dated the designs of Trevithick, Blenkinsopp, Hedler and Netphenson on that the early locomotives were but little better than stationary engines on wheels—upright cylinders working beams and other pearing being main features in the designs. It was not until 1520 that George Stephenson after building several unsuccessful locomotives of the Puffing Billy class produced his famous flocket, which comprised all the elements of the modern locomotive.

In 1865 Puffing Billy" was placed in the Victoria and Albert Museum London where it can now be seen resting upon some of the original fish-beliled rails al ready described.

To get an idea of the enormous increase in sins and weight of locomotives since the days when Fuffing Billy was at work, we will take the mammoth freight engine in use on the Actheson Topels and Santas Fé Railway which is the largest in existence. This iscomotive was described in the Sciamrizzo Ammican of June 17th 1011 for which reason duly a few dimensions need he repeated here for the purpose of comparison. The sende weight 2005 tens, the tender 117 tons, making the tend weight 165 tons, it is indeed over all to 126 tent for increase and the sender weight over all to 126 tent for increase.

### The Merger of East and West

But there is neither East nor West Border nor Breed nor Birth
When two strong men stand face to face tho they come from the ends of the earth!

In the "Ballad of East and West," Kipling tells the story of an Indian border bandit pursued to his hiding place in the hills by an English colonel's son

These men were of different races and represented widely different ideas of life But, as they came face to face, each found in the other elements of character which made them friends

In this country, before the days of the telephone, infrequent and indirect communication tended to keep the people of the various sections separated and apart The telephone, by making communication quick and direct, has been a great cement ing force It has broken down the barriers of distance It has made us a homogeneous people

The Bell System, with its 7,500,000 telephones connecting the east and the west the north and the south, makes one great neighborhood of the whole country

It brings us together 27,000,000 times a day, and thus develops our common interests, facilitates our commercial dealings and promotes the patriotism of the people

### The Chronology of Aviation

THE Scientific American has received from Mr. Hudson Maxim and Mr. William J. Hammer, a limited number of the reprints which they have just saused of the very complete "Chronology of Aviation, originally prepared by these gentlemen for the World Almanac of 1911. The data embrace the essential facts relating to serial progress in addition to a short historical riferum, one finds herein tables giving altitude records, speed records, quick starting and slow-speed records, passenger carrying. English Channel and other over-water flights, cross-country flights, notable distance and duration flights, etc. There are also statistics relating to accidents and data relative to pherical and drigible balloon or airwhos, etc. Of no small interest are the tables giving the most important flights of the Wright brothers. There are doubtless many readers of the Scientific American who are much interested in this subject and how would be glot to secure a copy of this interested in this subject and how would be glot to secure a copy of this interested in the subject and how would be glot to secure a copy of this interested in the purchase. (Concluded free, page 137.)

fifth of a mile in depth; where a gleam of light never penetrates, where the temperature wanders down to the ers down to the vicinity of freezing, and where the pressure is as great that all asimals living there must great that all animals living there must be more or less adapted to such as a exist-ence; their systems being perusested with water to offset the pressure. When brought up it was inconspicuous. It at-tached itself to a bail, and when taken tached itself to a balt, and when taket off, uninjured, recembled a ball of white tiesh about the size of a small apple.
When placed in a tank in the aquartum it When placed in a tank in the squartum is remained inconspicuous for days. But on-night the watchman in going his rounds, saw a splendid column of white over on-foot in height and expanding as much more across the tentacles, looking, said, like a miniature volcano; its fit tentacles being pure white and resembling tentaces being pure wine and resembning clouds against a durk sky. In the day-time the anemone reduced itself, by ex-cluding water, to an unnoticeable bulk; at night gradually increasing in size by pumping in water, taking the shape of a graceful perfectly symmetrical pillar. Then the pure white tentacles would begiu to appear and elevate thes performance which I observed through the courtesy of the old soldier who is a night watchman at the little aquarium at night watchman at the little aquarium at Avalon. Gradually the anemone would rise in a miraculous manner, like the mysterious plants of Persia under the hands of a fakir, until it stood firm and rigid, a spiendid creature a foot or more in height and six or eight luches acro the tentacies, which were pure white, sug-gesting the name "sea-ghost," given it by one of the men.

derful anemous, which might be called a sea-carnation, or used as a model by an architect when it reduced its size. This mplished by a sudden restriction midway, or a little above it, in the column which, apparently, forced a large amount of water from the column. The support thus removed from the enormou on or tentacles, the latter fell over until they almost touched the bottom, and the anemone had the appearance of having been stricken, or struck down by a heavy blow. In a few moments the restriction increased and the pure-white fluted tentucles began to disappear, drawn into the body mass which now impercep ibly settled down upon itself, giving the observer the impression of being witness to a miracle, as the giant grew smaller and smaller until in a short time nothing and statier until in a short time notating could be seen of the splenders of a few moments before but an inconspicuous mound of flesh, but a few inches high, perched upon a water-worn pebble four inches long, clinging to it by the seekling disk possessed by most anemones.

### Fighting the Plague With Scap and Petroleum

THE authorities of the Dutch East Indies are continually fighting the danger of the plague, which threatens the communities especially in the harbor towns, where rate from the incoming ves-

els spread the disease germs.

1 Dr. Pill, Government physician for the Dr. Pill, Government physician for the hncbor of Socrabia, has now found that a mixture of petroleum and soan, applied freely to the localities where the ratis warm, will effectively destroy their fisan and with them the plaque beddil. This new distinctant is obsepte and more effi-cacious than carboic acid.

# DELCO

ELECTRIC CRANKING LIGHTING IGNITION

### The Nineteen Fourteen Delco

Delco equipment for 1914 marks probably the highest type of electrical apparatus ever made for motor car service.

Recognition of this superiority is found in the fact that our entire output for this year amounting to 100,000 equipments has been sold and we are still unable to meet the demand.

The 1914 Delco is simpler and more compact in construction. It is higher in power and quicker in operation.

And—if such a thing is possible—it is more effective.

It is the Refined Delco—fundamentally and mechanically the same as the first Delco System—yet a somewhat more perfect product—due to the experience gained in the production of more than 50,000 Delco Equipments now in use.

And it is as dominantly in the lead today as it was two years ago, when for the first time Delco Equipment made the electrically cranked car possible.

And now get this thought firmly fixed in your mind.

Delco equipment occupies a dominant position today, not simply because of its ability to crank an engine—

Any electric motor properly attached to a car will do that so long as it has a full battery from which to draw current—

The Delco System is a success because it cranks a car in demonstration and then keeps on cranking it in actual day after day service

But even that is only half the story—the vital element in successful electrical equipment is current control—the battery must be kept fully charged all the time—no matter whether the car is driven fast or slow—no matter whether

much or little current is used for cranking, lighting and ignition—there must always be a fully charged battery from which to draw more current.

Delco engineers have solved this vital problem

Thousands of Delco equipped cars that have been in use for one to two years have never been hand cranked, neither battery nor motor has ever failed to respond when called upon.

That is why the Delco System has been selected by many of the foremost motor car manufacturers of America as standard equipment for their cars.

That is why Deico Equipment has come to be about the biggest selling asset that a car can have.

### The Third American Road Congress

E commend to the attention of everyone who is interested in the subject of transports tion, the meeting of the Third Road Congress, which takes place in Detroit from Sepsuid that transportation and civilization go hand in hand, and even a rapid survey of the pages of history will show that at least with regard to some of the broader phases of civilization, particularly those of a commercial and industrial character, there is a very infimate relation between the two. The masterful and fargighted Romans understood this fact so well that the road builder followed close upon the heels of the conquering army, and from the august city on the Tiber there industed a network of roads. Intelligently hild our and most excellently built, the greater part of which stands to day as a monument to the wisdom and ability of that great people
What was true in the days of the Roman Empire is

trelly true to-day; and we need not go beyond the larders of the United States for proof that abundant and excellent means of transportation is one of the most potent agencies in the development, not merely of the physical but ever of the moral and mental growth of a people. Would it be very far wrong to slate that the most active agent in the enormous male rial development of the resources of the United States during the post built century has been the steam rullroud? If cominge, resourcefulness and hard work alone could have brought about the present conditions of amuzing weight and prosperity, the hardy pioneers who drave their was westward in the rartler years of the Hepublic, would have perfouned the task. But at the most thes could do little more than merely locate the natural resources of the country, and await the day when some adequate and widely-spread system of trans-portation would be available to bring in the skilled and meskilled inborers and carry out the products of

The yest rullroad system of the I pited States, comprising some 250,000 miles of track, stands to-day as a practically completed task at least, so say the lead ng railroad operators, who are best qualified to Judg it now remales to supplement the work of the rull roads by building a system of interconnecting high ways, which will do for the tructs of country inter venlng between the various branches of our railroad system, what the system itself has done for the coun try at large. Had the sidmilian and farming districts ed any means of transportation to and from the ralloads, or between the various towns and from the randoms or netween the various towns must villages, other than the from wagon and the biggs, the call for a system of well-bulk highways would have been imperative. The rapid development of the automobile and the motor track, however, has given an enormons impetus to the agitation in favor of the construction of better highways, and we do not h tate to rank the good roads novement as one of the most important before the American people to-day.

In instification of the foregoing statement, we make certain facts recently recorded in this Journal by Director of the Office of Public Romis In an article unid-shed in our issue of September 6th, Mr. Logan Waller Page drew attention to the following facts. That during the year 1912 automobiles in the United

States outd in registration and thense fees \$5,638,878which exceeded the value of exp mobiles from this country in the whole of 1900; that in 1911 we experted automobiles to the value of \$16,-924,361, exclusive of parts of the machines, and in the following year lise total reached \$23,708,989; that in the same year, we had nearly as many aut-In New York Stale as there were in France and Germany combined, and, finally, that the total number of machines on our highways in 1912 was a round

#### Motor Truck Extension of Railroad

N interesting suggestion for refleving the con-gestion at freight terminals may be found in on mother page. The subject is an exceedingly com-pilented one, on which much could be written, but the article referred to, while giving but a brief outline the simution, offers the novel suggestion that freight terminal problems may be simplified by the use of motor tracks. In a small city the freight terminal is located near the business center and is of such cap ity us to handle all the freight expeditiously and afford ample room for teamsters. But us the town grows the business radius is increased, lengthening the aver age built of the tracks, while on the other hand more freight flows into the terminal, producing congestion, so that although more freight is handled, the profit in it is proportionately less. The larger the city the more valuable is the real estate around the terminal, making it costly to expand the terminal so that it can acco the freight with the same facility as it did in the beginning. To move the freight terminal to new and more commodious quarters, would in most cases be unprofitable to the railroad, because of the pital invested in the original location, and it would certainly be disadvantageous to the shipper or mer chant because of the greater length of haul required.
However, if motor tracks are used lastend of hars

drawn trucks the conditions are completely change for with its ability to cover the ground more rapidly. un extra bant of three or four miles is far less serie in a long delay at the congested freight terminal Delays are advantageous to the horse because the allow him to reemperate, and store up energy greater effort. But the never-tiring motor truck should be kept on the move all the time, because only when it is to motion is it giving any value in return for the enultal layested in fr

Hence, Mr. Niles argues that it might be advantagcons to a ralliond or a group of rallroads to establish or more annex terminals which will divert part of the freight that now closs the main terminals and which would be really accessible to motor trucks. The suggestion calls for a great deal of study, and aithough there are many difficulties that would have to be overcome, it is an exceedingly attractive propositlou il would mean the extension of the railroads to final point of delivery

Because delays to fooding and materdlar floure as dend loss against a motor truck, efforts have been made to reduce this period to a minimum. Trucks up provided with mechanical loading devices, riso with separate bodies which may be founded or unloaded while the truck is in 11 unsit with another body. It might even prove practicable to transport the motor truck bodles fully louded on that curs. A flat cur is nine fee , so that if the bodies were mounted transvers on the car, they could be made at least time feet long which would be ample for the ordinary motor truck The truck hodles mounted on rollers could chassis then be loaded by the shipper, hauled to the ratirond then be longer by the shipper, names to the ratirond, rolled upon the flat cat by means of a which, clamped in position, and there at the other end of the line, be taken off on the motor track chasses in the same way and hanted off to the merchant's warehouse loading and unloading would thus be redu to a minimum, and would prove advantageous not only to the consigner and the consigner, but to the railroad us well, for the curs would be released almost immediutely on arriving at the freight station. Farthermore If the goods were properly packed at the factors it might be possible under certain conditions to deliver direct to the consumer instead of the warehouse.

Another promising development is the motor truck roller. In a paper by Mr. Morgan Citiey, printed not long since in the Engineering Record, it was proved cancinglely that a motor truck shows its greatest efficiency when hauling trailers. In other words, a notor truck can pull much more than it can carry. His tests showed that a 3 ton motor truck could matu tain a sustained draft of more than 3,000 pounds, and that two trailers each loaded with five tons would require a draft of from 750 to 3,000 pounds. His table that the cost per truck mile with a motor and six trailers varied from 0.258 cent per haif-mile hauf to 0.103 cent per ten-mile haul, while the cost for a motor truck alone varied from 0.480 cent to 0.176 cent. By this it is not meant that the motor truck hauls a trulu of six trailers at a time, but only five, wellte black are two loading and two melonding. Theilers are not being made for this purpose, the wheele of stiller wall track with those of the motor truck, so light being in no difficulty in turning corners or threading a way be-tween obstructions. If since a method of handthing freight should prove practical, motor trucks would probably be materially changed in design, because the would not have to support any load except their own weight. Thus we would have railroad freight trains quickly converted into trailer trains hauled by trucks or motor tractors to place of locomotives

### Questioned and Unquestioned Factors in Evolution

IIEN, some fifty-odd years ago, the theory of organic evolution was first widely pub-lished, it met with violent opposition in cartain lay circles, opposition of which threadworn rem mants still remain smoklering here and there. Strange how preconceived and biased judgment will induce men to deny what on closer examination is found to be an absolutely irrefutable proposition, in fact a traisman axiom. For such is the principle of the survival of the fittest of the fittest. It is absolutely uncontroverible, be cause it is of the nature of a definition: The lit sur vives, it could not be otherwise, because we define the fit as that which survives. A mere definition can not he made the subject for argument.

So far then, the fundamental principle of the theory of evolution is unassatiable. But when we proceed to a more detailed analysis of the theory unhered in by Darwin, Wallace, Spencer and others, we encounter a number of problems that are far from being settled beyond dispute at the present day.

In the first place, it might be said, if the principle of the survival of the fittest is a mere definition, then what gain is it to science and munkind? The mere setting up of such a definition adds nothing to our previously existing knowledge, it would seem.

previously existing knowledge, it would seem.

Such an objection seems at first sight reasonable.

No one, however, who is familiar with the laws of schentific thought would be found to endorse it. For it is well understood among those whose life is spent in solving scientific problems, that the first step toward success, and often a siep more difficult than appears on the surface, is the cienr formulation of the prob-lem. Indeed, once the problem is thoroughly understood, its solution is often not far to seek. The great value of the principle of the survival of the fittest, is that it has served as a most valuable guide in direct. ing scientific inquiry.

True, the fit is merely defined as that which survives, but this at once raises the question: What are the characteristics of a given type by virtue of which It is fit? And thus we find ourselves ied on lo a sindy of the laws of mortality, feeningly, selective mating. heredity, and so forth. Nor is this justification of the ciple merely hypothetical the vast amount of work which has followed in the train of Darwin's epoch making publications, and the intensely practical results which have flowed to the plant and animal breeder (to mention only one example), speak more con ingly than the most astale philosophical argument.

in brief, us to the operation of natural selection, and its significance in organic evolution, there can be little But when we approach the question of the terial presented to unture for selection, we find ourseives surrounded on all sides by debatable ground. Does nature select from offspring which differs from its percents by small and gradual variations? If so, has upon earth existed for a period sufficiently long to account for the great changes in biological species which are known to have taken place? Or is the selec-tion made from among so-called sports or mutants, off-pring which for some ill-inderstood reason differ markedly and by a sudden less from its parent? O yet again, is such selection of well-adapted types as d by the luberitance of useful characters acquired by the parent within its life time? Probably each of ctors plays a part in the development of species, but to what extent is an unsettled question

incidentally it is interesting to note that in the case of man, and especially modern man, a new factor enters—the material offered for selection is created by a new process. Variation, mutation, heredity, all Thus the ear seems to have been evolved from a structure corresponding to the gill cleft of a fish. By ture corresponding to the gill elect of a lish. But that arilficial end of undern man, by the sid of which be can hear and understand conversation over a thou-sand miles, is not a physiological product of flesh and shood, but a thing made with human hands. Here we are no longer bound by the fetters of slowly accumpwe are no tonger sound by the Peters, of sowers secular, and a lated variations, how at the mercy of captrious saudie. House, Man is free to give hie genius free play, and as the result the past century has seen used: a food tide in evolution as must be wholly unascended in the millions of years of our cartilla man, history.

#### Electricity

Receive Tan in a Ferfums Shep.—With the object of Incing obsorbmer into his sliop, a perfumery merchant of New Orleans, La., has placed an electric fan in his doorway to carry out into the street the entiting odors of his shop. An attendant with an atomizer sprays the fan with various perfumes.

Telephone from Helland to England.—A submarine telephone is to be laid between Holland and England. The length of the sable will be no less than 105 miles. According to the present project, the total expense will be near \$8,000,000 and will be borns conjointly by the worountries. On the Holland side, the starting point of the cable will no doubt be at the locality of Westkapelle in the island of Waloberon.

pelle in the island of Waloberen.

Spead of Hertalan Waves.—Experiments with Hertalan Waves.—Experiments with Hertalan Waves between Toulon and Paris by Mesers. Abraham Dufour and Ferrié show that the waves travel with a spead of 295,990 kilometers per second. The spead of light waves is 200,000 kilometers per second. The Rapariments are now to be conducted to determine whather the spead of Hertalan waves across the sea is the same as that over land.

the same as that over land.
Wiesless Trials Dispatching.—After a careful investigation the Superintendent of Telegraphs of the Atchison,
Topelss and Beats & F. Kallway has come to the conclusion that it is not advisable to install wireless telegraph appearates along the realized, not only because
of the expense of installing and maintaining the stations,
but also for the reason that wireless telegraph communication can too easily be interfered with to make
it sufficiently reliable for railroad use.

The Largest Electric Mins Holst, says the Electrician (London), is being installed in 8 South African mile A shaft is being equipped with a 4,000 horse-power boist to be operated on the mains of the Vistoria Falia Power Company, without any attempt at equilatation of the maximum and minimum power demand, which means that the motors will require something like 7,000 horse-power during acceleration, resulting in a load of 9,000 horse-power on the transmission line. The equipment will consist of two 2,000-horse-power continuous-current motors, one at each end of the drum shaft of the holst. The motors will receive current at 5,000 volts from a motor generator converting the 65-cycle 3-phase current to continuous current. The motor species of the converse induction motor generator converting the 65-cycle 3-phase current to continuous current. The motor generator will comprise a 5,000-borse-power 3-phase induction motor, operating on a 2,000-volt circuit, directly coupled to two separately excited continuous-current generators, each of 1,650 kilowatte capacity.

Magnetic Separators.—In different kinds of granding mills it is found that fragments of rion cause disasterous explosions, as for instance in an English oil works where fron turnings in the mills gave sparks which set fire to the inflammable material. A number of works in Europe, and especially the ones which suffered from this class of secident, are making use of magnetic separators in the shape of revolving drums. Inside the drums are powerful electromagnets which cause the fron particles to adhere to the surface of the drum, so that the pieces are taken up and delivered over to the other died where a suitable scraper takes them off. In the improved types, the inside magneta have as winding of aluminium wire, self-insulated by oxide, so that the colls are heat and moisture proof and the devise is very reliable. Such magnetic separators are recommended for cocco or bone mills, chemical works, coal crushers, sugar refineries and grain mills, as well as in the textile industries. We may mention one case where iron particles caused a fire in a Wurtemburg spinning factory, where \$20,000 worth of cotton was burned. This class of works, together with oil milis, appear to be the most in danger from the presence of iron particles.

presence of iron particles.

A Historic Gavel.—At the opening session of the Illuminating Engineering Society in Pittaburgh, on Sept. 22d, Prof. George A. Hoadley of Swarthmore College presented to the Society on bending of the Philadelphia section a gavel that forms a miniature achibit of the development of artificial illumination in America. The candle is represented by a tin handle from a candle making apparatus; the oll lamp by two pieces of iron obtained from a bracket, the design and making of which were supervised by Bengiamf Pranklin; the gas meantle by a vial containing the original Weisbach lighting flutd, under in the Weisbach laboratories in 1888; the arc lamp by an electrode used in the first magnetic arc lamp in 1903; are lighting by a piece of single conductor cable installed by the municipality in Philadelphia for are lighting about 1890; the incandescent lamp by a 6th that Thomas A. Edison used in his sarty experiments in making paper flaments in 1879; the vacuum table hamp by a piece of electrods of one of the Moore-light violum; tubes, exhibited at the first New York societies above in 1809, lighting service by a piece of the first Edison Service side installed in Philadelphia; while has a fedurator in the complex of the first Edison Service side in the state of gladelphia; while he are installed in Philadelphia; while he are

#### Science

The Seventh Centenery of Reger Bacon's Birth will probably be celebrated in England nast year by the erection of a statue in honor of this serily champion of experimental science, in the Natural History Museum at Oxford, and by raising a fund for the publication of his works.

The Buyz-Ballet Medal of the Royal Academy of Sciences of Amsterdam, which is awarded every ten years for distinguished work in meteorology, has just been granted to Prof. H. Hergesell for his investigations of the upper atmosphere in subtropical and circumpolar regions.

A University for Central China.—The augmenton to establish a university on cocidental lines in central China is accounting much interest in Greet Britan, where the contral china is accounting the same of \$250,000 from the scattering the same of \$250,000 from the Company of th

Solar Observatory in New Zealand.—The long-felt need of solar observatories in the southern hemisphere has been met in recent years by the establishment of such institutions in India and Australia, and now it is anounced that one will be established shortly in New Zealand. The Metalf Count Observed by Brooks.—The now omat recently discovered by Mr. Joel Metalf has been observed by Dr. William R. Brooks at the Smith Observatory, Geneva, New York. It is in the northern sky just above the bead of the Lynx, and its motion a northerty. The comet is telescopic, rather faint at discovering the support of the support of the country of the supposed to the Sun, cocurred on September 14th, in position right as month of hours 10 minutes; declination north 07 degrees 12 minutes.

The Sames Observatory at Apia, originally established in 1902 as a temporary piace of meteorological and gen-physical observations in connection with the international antaretic expeditions, has gradually assumed a permanent status and become the most important scientific institution in the South Seas. It is conducted under the suspices of the Royal Bootley of Sciences at Obtimizes, and supported by the German government, which has just authorized a substantial increase in the revenue of the institution. At frequest interests and widnesses on the total control of the co

As Exhaustive Study of the Cartia Family, with respect to taxonomic geographic and economic features has been undertaken by the Department of Botanical Research of the Carceger Institution, N. L. Britton, director of the New York Botanical Garden, and Dr. J. N. Rose, of the Smithsonian Institution, being in charge of the work. Dr. Rose has been studying the great reollections of Castoseen in European The field work will begin with an exploration of the West Indies and the north coast of South America. The field work in the deserted of Argentina. A large number of volunteer collectors and botanists in the southwesters United States, and about twenty (Jovernment supploress, are seeding in material. Two or three years will be apent in assembling and organising the collections. A series of volumes dealing with these highly specialized plants will be published.

Work of the "Anten Dehrn."—Dr. Alfred G. Mayer, director of the Department of Marine Biology of the Carnegie Institution, calls attention to the broadening of the work of his department made possible by the acquisition of a stemen 70-1t. twin-ever yacht, he' Anton Dohrn." The whole West Indian-Florida region has been opened to the southiest of Dr. Mayer and his staff, and it is proposed to commence a series of biological oceanorpship researches embracing the interesting region of the Carlbbean Sea and the sources of the Gulf Stream. Afreedy a order of 570 miles has been made among the Bahamas. Thus we have in America a parallel to the remarkable softwittes of the "Mishel Sam" in European waters. Dr. Mayer keyz: "It should be a source of reget to us in America that our country, which during the nid-decade of the nineteenth country under Maury and Bache led all others in the selectific study of the sea, should sow have fallen into an insignificant place in such researches. Our country, which fostered he labors of Leuis and Alexander Agassia, and of Pourtalès, Signess and Searchuse (sic) respecting this important field of study."

#### Aeronautics

The 1913 Gordon Bennett Balloon Race.—The spherical halloon commusion of the Acro Club is occupied with organizing the Gordon Bennett Cup event, which is to take place in October. The following prizes will be awarded. First prize, known as City of Paris prize. \$2,000. Second prize, \$1,000. Third, \$500. Fourth, \$300. Fifth, \$200. Also objects of art As usual, the start will take place from Paris

Competition for Highest 1913 Total Mileage.—Several of the French acceptance pilots are competing for the sup-which is to be awarded for the longest total distance covered before December 31st. Fourny is at the head of the last at present and has been making flights every aday in the region of Paris for the last two weeks, having at last accounts footed up 9310 kilometers (about 570 miles)

The Michella Bomb Dropping Centes. - The several part of the scenal larget contest for the Mechan purior \$30,000 held during September shows some interesting conditions. The rules call for the placing of 15 abot or imitation bombs of 6 unch diameter and 15 abot or imitation bombs of 6 unch diameter and 15 pounds weight, with seroplasse philips at 200 meters (656 feet). The target traced on the ground is a circle of 66 feet diameter. Different zerordowne shave entered pilots for the tests, there being the Farman at Buc, with 9 pilots, the Stamps accordowne with one Farman seroplane, and the Chalons and Vidamée, each with one pilot. Six of the competitors are army offices.

The Bonnet Prize for an Automatic Stabilizer Performance. In view of the progress which is being made in the way of automate stabilizing for aeroplanes, the National Averal League of Paris is promoting the question Engagements are now open at the League for the latelyfounded Henri Bonnet prize, to be awarded to the first plot fluring in a wind of at least 15 feet per second, is able to cover a distance of at least 12 miles without touching the levers for the vertical steering ruidder or for the alterons. The horizontal steering ruidder is to be independent and can be used on the occasion, as the object to to have an automatic stabilizing in the vertical

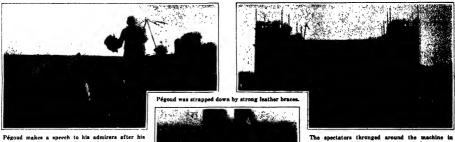

Monoplanes and Bijanes Compared.—For newplanes of equat span, cross-section, aspect-ratio and angle of inclination, the monoplane has about 15 per cent more lift than the lipiane for equal speeds, according to F Handley Page, the English designer. A monoplane has a smaller resistance than the corresponding biplane, a support of the section of the se

The French Gordon Bennett Competition. The following are the competitors which were drawn by tot at the Paris Acro Club for the Gordon Bennett Cup eliminatory trais for acroplanes. Dependines monoplanes will be monited by Prevoya, Gilbert and Rost, Bardi monoplanes by Denocut and Chemet, one Brögnet biplane by Brögn, a Nieuport monoplane by Espanet and a Pomer monoplane by Vedrines. The trais take place September 26th, and the rules call for a run of 60 miles Competitors are allowed to make three trasts and to choose the time of starting. The first three acroplanes classed in this event and offend the French colors in the Gordon Bennett raws, which is fixed for September 20th, which the next three plots will form a reserve.

War Experience in Air Scouling.—Both in the Tripolitan and Balian campaigns the aeropiane was used with good effect. In Morreco air scouling frustrated ambushes, forestalled unexpected attacks by superor numbers, and alleviated the mental tomson of the commanders, because they were always enabled to know the strength of their Arabic and Turkish encemies. All this was merely of a defeasive nature, for the character of the country and the climate made it impossible to decide the war by was offensive operations in which the air soon might have been all-important. The aeropiane might have played an important part in the Balians had the aviation corps of the allies or of the Turks been propared. Unfortunately, they were not organized to move with the field forces. Like sage artillery, they reached the front list. What they really accomplished is still the secret of the observer-officers and of the gene al staffs. The pilotos of the machines were not taken into the confidence of their passenger observers. Indeed, they often compliance that they were acting bludly, and that they could not perform their functions efficiently as a consequence. In a seuse the air service in the Balkans was at times of a defensive nature. It frustrated salhes from beinged fortifications because the air scuts saw what was coming and could notify their commander to prepare themselves. Although not decisive factors in the war, the machines become indepensable. Any news about the aenew appears indepensable.

### Turning Somersaults With an Aeroplane

The Remarkable Exploit of Adolphe Pègoud

Pégoud makes a speech to his admirers after his second somersaulting performance.

N hist week's issue of the Scientific American, In the weeks resource to the performed by Adolphe Pégoud in jumping from a fiving aerophaic with a parachute. Since that exploit was performed, Pégoud has accumplished the still more extraordinary feal of turning a somersault in the nir in a Bierlat monoplane Pégoud performed his somersanit twice, once at Buc on er 2nd, and ugain ut Juvissy on the following When the news was first cabled to this country. cay when the news was nest collect of this country, experienced aviators and designers shook their heads in doubt forville Wright, for example, was quarted as one of the skeptics. He pointed out, with others, that the gravity fuel feed of the aerophane would be cut off as soon as it was turned upside down, so that even a short journey in an inverted position seemed

or all that the feat was anquestionably perform as the accompanying photograph showing the machine unide down administratives. That it was accomplished at all is due to the fact that it formed part of a rol plane. Mr Wright was absolutely correct in stating that flight in an inverted position could not be maintained on a straight line for any considerable

The Bierlot monoplane used for these acrobatics was The inertor monopane used for these acrobatics was a single-senter of the XI type, built in 1912. The position and height of the upper rabate was stightly modified and the bracing of the fixed tail plane was reinforced. As one of our illustrations shows, Pégond. was strapped into his sent with leather braces passing over his shoulders. Rising to a height of 3,500 feet, Pégoid cut off his engine. Turning the nose of his machine down, he dropped almost in a verticul line. At a height of 1,600 feet

he putled his clocke and forced the muchine on its back. Thus he glided for five hundred yards at a slight downward angle Again Pégond worked his The machine as sumed a vertical position again for a few seconds. then straightened out in glide, and rame to cartle in its normal position

Pégoud states that while he was flying upstde down gasoline leaked drop by drop out of his fuel tank, and fell into his face The draft from the propeller blew it all over him like a spray "It was just tike being to a burber's chair upside down," was Pégoud's reply to the ques-tion: "What did it feel

It might be supposed that Pégoud is a inridened aviator. As a matter of fact he is only twenty-four years of age and took out his plot's certificate on February Sth last.

In our issue of May 31st, 1913, we recorded the somersault of Capt. Aubry of

the French army while flying a Deperdussin. The captain was flying against a wind of about twenty-two miles an hour At 2,500 feet, a series of violent gusts struck the machine. He was obliged to dive in order to sive gusts struck the top of the main planes, and placed him in a vertical position While endeavoring to man-ipulate the elevating rudder, he found the machine had nomine the elevating rudder, he round the machine had taken him in a perfectly vertical drop to less than 1,500 feet. Here it assumed a horizontal position upside down and proceeded to effect a tall-first vol plunck Somehow the pilot retained his seat. The machine then gradually assumed its vertical position again. Fiatten ing out, the captain flew to a spot about two miles dis-

Pégoud's feat is more remarkable becau liberately performed, not only once, but twice, l'égoud's performance has any value whatever, it she that monoplanes can be so constructed as to withstand even abnormal strains—it also shows that a pilot with n cool head and perfect control of his mach save himself even in a most perilous position if he is high enough from the ground.

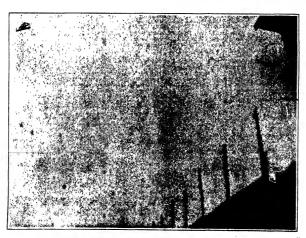

### The Nature of Radio-telegraph Waves

I N a paper read before the British Association for the Advancement of Science, Prof. G. W. O. Howe,

M.Sc., states that a very clear conception of the nature of the electro-magnetic waves employed in radio-teleg raphy can be obtained by considering those electro-mag-netic waves which exist in the space between the two conductors of a single-phase transmission line. If the conductors are fint, parallel strips, close together, and connected at the sending end to the terminals of an alternatur, there is a certain value of the non-inductive load at the receiving end which will absorb the arriving energy without any reflection. Under these conditions the current and voltage are in phase all along the ine, and the same is true if the line is assumed to be of infinite length. Line resistance and leakage are assumed to be negligible. It follows from this that the electric and magnetic fields at any point have their maximum values at the same moment. Instead of two maximim values at the same moment. Instead of two parallel strips transmitting energy to one direction, two parallel disks of infinite extent can be imagined with the alternating PD, applied between their contern. Energy would then be transmitted radially in all directions in the plane between the disks The earth could take the place of the lower disk, while the upper one could be represented by a conducting horizontal plane some distance above the earth. The waves produced would be truly cylindrical, whereas those employed in radio-telegraphy are spherical. If, now, the upper disk is replaced by an inverted conducting cone of infinite extent, with its npex almost in contact with the earth, the alternating PD, being applied between the apex and the earth, the electro-magnetic waves will be almo identical with those employed in radio-telegraphy and will vary in the same way with the distance from the sending station. This imaginary multi-directional trans

which Pégoud turned som

a lower plane (the earth) and an inverted cone, lends itself to simple calculation, because, like an ordi-nary transmission line, and unlike the two parallel disks, it has a constant inductance and capacity per mile. If the angle between the cone and the earth is 70 degrees, the relations between the magnetic and electric fields near the earth's surface and the total energy radiated are identical with those existing in the ordinary radio-telegraphic wave. As in the transmission line already considered, the current and P.D. will be in hase at every point, and therefore, the horizontal magnetic field and the ver-tical electric field due to a sending antenna are not 90 degrees out of phase but approximately in phase, except immedi-ately about the antenna. This also follows from the fundamental equations of a progressive, as distinct en a stationary, electro-Tring out to mile

Handwriting and Human Efficiency A Psychological Survey Based

Upon Facts

By William Leslie French

In this country the Science of Graphology has been utilized but alighily until very recent years. And the reason for this is that its practical application to the conditions which make for human efficiency has not been tested or recognized to any marked degree. However, many who have investigated this method for analysing character, montal and bylacial traits and teadencies, have absolutely become convinced of its great utility.

In this connection the oridance offered by a well-known corporation lawyer is perjoint. Whenever it is necessary to secure complete information concerning the character and habits of witnesses," he states, "I rely particularly upon the data furnished by a graphologist in order to safezuard my clients' interests. In a recent iswuit tuvoiring many thousands of dollars, this efficiency expert demonstrated from when the records that the person under cross-examination—prominent man—was first and foremost a liar and a crock, that has statements where called to retrify would be false. Later he strengthened his remarks by priviling that the witness had forgred his signature. This evidence proved to be correct in detail. Within twenty four hours tilb witness had fide to parts suknown:"

four hours this witness had field to parts unknown: To give an illustration, a few months ago, in the office of one of our large corporations, the secretary of the firm said opening his mail. After consigning a number to the weste-basket, he uttered an exclamation of diaguat. "Well, ill he juggered! I advertised in the paper for a bookkeeper and these are what I get This is one sample"—showing a letter across the flattop desk. "Tid not a handwriting expert, but if this fellow's writing does not show his lack of flatess, till resign my jostition. And this is not any first experience by any means. Every firm is un against the same proposition. Half the time, if the references are good, the man is crocked or given to bad habits which make

proposition. Hair the time, it the references are good, the man is crocked or given to bad habifs which make him worthless in the long run. Number three is the letter. Note the general style, Irregular, careless, somewhat erratic, with the junctual content of the proposition of

Number four is a marked contrast, as anyone can see This individual is orderly, systematic, cautions and industrious. The style is uniform, with punctuation carefully piaced and the small letters even in height and pointed at the top. The long letters are well developed above and below, the "t" crossing being No. 2.—Salesman with a vivid imagination and with the quality of evasion.

to pariginal ...

neither at the right not left of slem. A person se signs would be able to occupy any position which requires ubility for office work, backkeeping, banking or similar lines. He would be industrious, punctual

and do his daty at all times Number one, the writing of a woman, helrnys her forceful way of blinking, as appears in the connecting stokes, the "t" crossing and firm pressure. Her tact is found in the first small letters of words being larger at the beginning than at the end. An occasional break between letters as in "borough" gives her intuition, a raluable adjunct which many successful executives also have. A clergyman who is amuzingly skillful in also have A clergyman was a managey satisfactoristing mose for the projects wrote specimen five. His self-confidence, will-power and ambition, signified by the heavy pressure. "I' has sloping discovered the right, and apward pounding of his words across the page, combined with the fuel and diplomucy signs us before, force blin lute the executive class, despite himself, as it were

There is a saying that he who does not write straight will not think straight, net straight, or be straight So to the writing of number six appear all the pensigns which mark the crook at heart. Observe that the lines audulate, the small letters varying in height and size, of which some are close ingefier and closed.
The spaces between the lines are not very even, and The spaces netwern the line are not better the finds are rather abrain. Should the occasion arise, a person possessing these hall-marks would not hest tate to jugate petty eash, butnige in check-killing, or lake graff at every opportunity.

In specimens numbers seven and nine appear two an ejectment numbers seven and thin appear two other types of writing which throw them very closely into the same class. The signs are alike, though, as anyone can see, the slyle of both is markedly different The first is a good example of a person who would be crafty, use canning, and cover his tracks rather suc-cessfully. Though his cowardice is shown by the feeble pressure, he could lie skillfully, for his "a's" and "o's" are tightly closed, the small letters being pointed at the tor. The second is another who, on account of the top. The second is inducer who, of necodal of writing backband, has a natural feulency to devious uces, while his ubility to the shows in the looping of the "o" in "of."

How strikingly different are the scripts of numb Both individuals write a straightfor ten and eleven ward hand with no ways movement, small billers changing in height and size, or the spacing between changing in negati and size, or the special between these and letters uneven. Each leaves plenty of room between the letters and the fluids are not cal short. Thus, honesty, sheedly, truthfulness, frinkness and adherence to duly are received. In any form of work, people who exhibit such peudralts can be relied upon people who exhibit such pen-traits can be reded upon to perform every function without being "packed up" by the manager of the office Writing at the angle of forty-like degrees, the pressure being even throughout, endows such with a mercantile conselence which per veuts any destington whousees. As handwriting thinks of a brandwriting indicates moral collections, it also reveals the values kided over the work for which people are reveals the values kided over the wheel people are

fitted, along commercial lines, of which the following ure additional examples

if it is necessary to engage an individual for the position of a salesman bond, advertising, real estate or insurance—the general features found in numbers of hostinuce—the general returnes forms in numerics two, eight and twelve will appear. As you will note, these specimens are quite dissimilar in style, but the mental instedients are there. Each pounds the paper with force, energy and determination, as is shown in henvy, hold, uniform pressure throughout The big generous capitals give self-assurance, confi dence and a helief in their own ability to succeed, which is increused by the high looped letters above the lines us the "h's" in number two, the human brouco-break-ing capitals "I" and "P" in number twelve. All give ring capacities. It add to the monoce to wheather the writers handlandout, the power to wheather the proposition which they may be exploiting, and then concline others. To be suite, they close their small bits mult os? The issuit sign of secretiveness, but in these cases it merely signifies that they know when is keen their months shut-an excellent sign in a sales

Anyone can see that the nerson who penged number thirteen has about as much self assertioness as an anemic kitten trying to cut down un ouk. He crosses his "ts" in that quiet fushion which shows that he would present a business scheme or plan so quietly that the average man would have an engagement for that the average man would have an engagement for unert. The delicacy of his writing and pressure de-bars him from selling 'blue sky," accommanded by the fact that, and his predictors, his script has no curved base-the the skyn of being rable to evade the mestion or dube a carbons and periment customer. This skyle indicates (finality. Would you care to employ this type to sell goods?

As engineering, invention and creative power play an important part with corporations la-day, it is of interest to learn what grokes in combination show capacities in these directions.

Where a person has naturally a scientific bent, you

will find that the writing is, as a rule, perpendicular, backward or sloping slightly to the right. The small letters will be low, pointed at the top or square, and the connecting strokes of words and letters well formed Frequently, they are shaped like figures or chemical signs, angular rather than rounded. (See especially er fourteen)

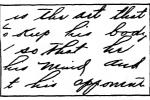

Examples fourteen and sixteen are excellent types of Examples fourteen and stateon are excessed types of persons who have a natural gift for mechanics and engineering. The first gives every sign, the second betrays the same formations, but the power of concentration is remarkable besides, indicated by the small

No. 16.—Electrical engineer or one who would do well in this class of work.

precisely-formed low letters This man's mind would apply liself to minutize to an extraordinary In contrast to that of his companion, number fourteen, his metier would be electricity in preference, because critical investigating trend shown by the small letters pointed at the top and the sharp up and dawn strokes, as in "f" and "y." He does not possess us much liking for rugineering problems as the other, since his "h" does not extend so far above the baseline.

ed health is the first requirement for a man to do effective work, enabling him-all other things h ing equal-to hold his position and to advance Speci-

men unmber fifteen presents a perfect billet of health. serfe for may insurance company to passe un, for the even, sleady flow of the wriling, the firmness through out, and the well-formed rounded curves below the lines, signifying n love of athletics and outdoor sports "y's"-all betray physical exuberance and vitality-a man who is in fine physical trim

Now look at number seventeen, and see if to the naked eye one can spot any difference with that above. Apparently, there is the same kind of pressure, and like curves below the lines. But, unfortunutely for the writer, there is the remarking of the strokes in

No. 18.—This specimen shows all the combinations of small "s's" and "o's," indicating secretiveness and caution.

'art," "so," and in the last half-obliterated word, re veals, under the glass, that this individual is addicted to the excessive use of cigarettes and morphise. He is u big, sirong, husky fellow, naturally as powerful as a hull, but beginning to weaken. He lost his position a good one—because he was too singgish and sleep (in the surface, he appeared to the average onlooker to

In reading the characters from a given specimen the following additional rules should be ob

Where strokes constantly appear it indicates a natural and strong characteristic. A stroke which is occa slountly seen betrays an occasional trait, while one

No. 19 .- The large loops of the letters above the line indicate highly developed imaginati

which appears regularly and is exagge abnormal characteristi

abnormal characteristic.

The general signs which have to be considered at the foundation of this science are the manner in white a person makes his connections, whether the writing is large, small, or intermediate, round, sharp, or angular Writers who make their capitals large, with the

wraters was made their capacity args, with the small letters high, possess a desire to do great things, are enterprising, independent, and take pride in their achievements, and are liberal in their views. They are better at generalities than fitted for details Many extravagant spenders write a large hand sh wide spaces between the lines and letters.

Small writing gives the writer concentrate the power of attention to details, with carefulness, a fine of observation and a good critical faculty, es sense of observation and a good errical actuary especially if the letters are sharp at the top. The capitals may be either small or large, for their height has a different significance, which will be touched on later. Where the small letters are neither too high nor too

the intermediate class—the individuals are well low—the intermediate class—the individuals are well-behanced, usually, with the qualities of good judgment. Intellectual and material order, a fair amount of co-contration, and practical common sense. But the reade-must remember that other signs may modify these

People whose writing is sharp, with clear-cut cor-ers, have much power of resistance, some of their ners, have much power of resistance, some or tractirative long rudeness, severity, sectionability and temper. Those who pen a well-rounded band show the opposite characteristics. Mildness of disposition appears, and such writers are easily influenced by others, their power of resistance being less.

An individual who reasons clearly, showing a logical

mind, will form his connecting strokes carefully and even with a good deal of originality, there being practically no breaks between the letters of words. Sometimes there are additional signs, such as words being connected, also. The strokes of one line will not interfere ith the others, while a fixed style will be shown.

The slope of the writing is a most important feature.

for according to the slant you can determine the amount of affection an individual possesses. The normal slope

is close to forty-five degrees.

The "t" dushes pluy an important part in affecting person, character, and disposition. In many cases are the sign of temperament.

If the stroke is long, rupning upward, ambition, seal If the stroke is long, running ujward, suntion, seen, love of enterprise, and enthusiasm are signified. Montal energy appears when the crossing is dashed to the right, frequently downward. When the "t" bar is blunt stubboraness is betrayed, the man who will hauge on and stick to his purpose. A long steady stroke across the "C" stem shows deliberation and moderation. Will power also appears A weak, flashy stroke hetrays vacilation and little will to achieve, the person being easily influenced.

The capital letters are also very significant. When the capitals are very high and large this shows cone and vanity, and linese qualities are exaggerated if flourishes appear. The lower the capital the less pride there is. If the first stroke of the "M" is higher than the others, independence, pride and social ambition are shown. This applies to the "N" and "W" also. When the outlines of the capitals are well formed and not loo elaborate, simplicity; and artistic ability is shown

by curved and print-like formations, usually shaded.

The final strokes of letters give much valuable in formation, and are one of the most valuable clues to Abrupt flusts show selfstmess. When they curve upward and outward, generosity and sympathy. A terminal stroke outling in a hook betrays perversity, one which would cause the writer to insist on his own ideas being carried out. A straight down stroke at the end of a word shows secretiveness and also a tend-

ency to be skeptical.

The small letters also have a special significance, and for convenience wike can be thus classified:

for convenience sake can be thus classified:

a Long letters which extend far above the baseline and are looped, especially ""k" "da" and "f"," give
imagination, also un toterest in things pertaining to
the mind rather than practical affairs. The looped
"t" and "d" give garrully, and if open at the top
they are the size of extreme talkativeness. The sharpening of long letters in this connection betrays reserve, and sarcasm, especially when the "!" is pointed. (Numter eighteen.)

When the letters, such as "y's," "g's" ar extend well below the baseline they rowed, when firm or made with a rounded curve to the right, excellent vitality and a good constitution. My interpretation

viality and a good constitution. My interpretation does not signs with some authorities, but I have always found it to hold good. "vie" and "g's" are tightly closed, secretiveness and caution are found; when they are upon at the top the tendency to talk too much is shown; and when they are looped—from; (Neunderinstease,). The backward stroke to the left of the "d," or, in this.

any stroke of this formation shows ampli (Number mineteen.) Service Additional Commence

### Snake Imbedded in a Log

To the Editor of the SCIENTIFIC AMERICAN:

One day recently my sawyer while quarter sawing a 48-inch white oak log, found a snake about one half noh in diameter imbedded near its center. The wood was sound and at first it was a perplexing question how a snake fully equipped for business had come there, but was sound and at nev it was a perpiexing question now a maske fully equipped for business had come there, but after investigation, I reached a satisfactory conclusion concerning it. It appears that when the tree was some three feet in diameter, a fire had been placed about its cares rees in diameter, a life had oeen placed about two roots and this had partly killed one side to the height of about two feet above the stump, but a new growth and completely covered the wound. In felling the tree the dead part, being perfectly sound but brittle, sud-denly gave way and splinters from the live part, some of semy gave way and spiniters from the live part, some or whem three or four feet long, adhered to the stump. The snake, no doubt, entered the log through the spaces made by the splinters, and was not able to extricate itself. The dampness of the river bottoms added by heavy rains caused the seasoned part at the end of the log to expand and thus entirely closed the aperture through which the snake had entered.

DELOS H. BACON.

### The Destructive Effect of Bullets

To the Editor of the SCIENTIFIC AMERICAN Quoting from the article "The Other Side of War, on page 162 of the August 30th issue of your esteemes publication, the assertion that, owing to increased rotation, the bullet acts not only as a club, striking a heavy blow, but also as a gimlet which lacerates the

heavy blow, but also as a giniet which lacerates the tissues, seems to stand in need of correction.

In order to produce a gimlet effect, the bullet must either have the shape of a gimlet or it must describe a spiral during the set of penetration. The former is a spirm during the sect of penetration. The former is out of the question, considering that the ridges made on the circumference of the bullet are trifling and run almost parallel with the length axis. Moreover, if we investigate how many turns a bullet makes in perforat-ing a human chost of say 9 inches diameter, the answer will be surprising to anyone thinking only of the enormous number of revolutions which the bullet makes during number of revolutions when the bullet makes during the whole path of its flight. As far as I have been able to inform myself, there is not a single small-caliber gun in existence, whether rifled at a uniform or increas-ing twist, which would permit the bullet to make more

ing twist, which would permit the bullet to make more than 1½ turns within the barrel, i. e., for an average path of about 36 inches. Since the rotational velocity of the bullet cannot possibly increase after the bullet has left the gun, but, possibly increase after the bullet has left the "gun, but, on the contrary, decreases rapidly as the bullet proceeds, it follows that the bullet, in perforating 9 inches of a human cheek, has made one quarter of one items within the chest! How can that produce or ra'ce isilly affect the laccration of the tensure.

In my mind the action of a rotating bullet could be better compared with that of an and, which as every-body knows can be passed with loss effort through, o. g., a number of layers of leather, if we rotate the handle. But the hole thus made would, if anything, be smoother than if we were to omit britation.

nance. But the nois truis made would, it anything, be smoother than if we were to omit rotation.

If, therefore, wounds made by small-saliber, high-velocity bullets exhibit any particularly destructive effect, it must be due to causes other than "gimlet action" of the bullet. Of these causes, one of the most action of the outset. Of these causes, one of the most plausible has been omitted in the explanation of Dr. Helme, to wit, incompressibility of liquids and semi-liquids. If a high-velocity bullet enters the cranium, the addition of the volume of the bullet to the (nearly) incompressible contents implies a sudden increase of pressure within the granium, possibly the equivalent of many atmospheres of pressure, which, though lasting of many atmospheres of pressure, which, though lasting only an instant, is capable of fully explaining the de-structive effect. Similar conditions prevail in the case of the human baddy: Contrary to the popular being, excepting only such pathologic cenditions which have expended the formation of gases, the bladder mover con-

caused the formation of gases, the bladder never contains air and liquid, but expands in proportion as the liquid accountate. If the liquid is confided, its walls collapse and are in a state of closest approximation. If a builder enters a filled bladder, the inertia of the walls prevents a correspondingly rapid expansion; because of pressure within the bladder and enormous increase of pressure within the bladder. Because of the wall-known advantages of a flatter triplertory, the avoidance of e-coalled "windage," and, penalty, the avoidance of "sumbling" of the builts, the rifining of gass, and with it the resistion of the small-coalline builder, does not add to the "oriently" of the friends. pis made. Mobuspi, Pa. A. StOMARK, M.D.

#### The Ten Greatest Inventions

W HAT are the ten greatest patentable inventions of the past twenty-five years? The Inventors Prize Contact which closed on September 1st brought Prize Contact which closed on September 1st brought in a large number of essays, but no two agreed on the ten greatest inventions. The wide divergence of opinion is shown by the following list, taken from a selected dozen of the essays. Furthermore, a poll of the editorial staff failed to show perfect unanimity on more than six inventions. The Editor is interested to know the opinion of readers of the Scientific America can on this subject and invites every one to send in his Here is the list, and quite evidently it include some that are not patentable, and some that do not properly belong within the 25-year period, but the reader must decide for himself which should be avoid-Acetylene gas from car- Kodak.

Pick out the ten best inventions in the list and send them to the Contest Editor before the 18th of October The result of the vote will be published in the SCIESTIFIC AMERICAN of November 1st. This number will also contain the essay winning first prize and the aunonnement of the successful contestant

### Two Trips Around the World

TVER since the time of Mugelbin, the journey around the world has held great attractions for travelers, and with the development of steam unvigation, coms-confinental railways, and all the modern auxiliaries of locomotion, the time required for the trip has been continually reduced

Nearly fifty years ago Jules Verne crented the character of Phileas Fogg, in his story "Around the World in Eighty Days," and since that time this imaginary trip has been followed by actual journeys of briefer

The desire for speed, however, seems to have reached limit, and although it is probable that still further eductions may be made in the time regulared to make the circuit of the globe, the relation of the iluration of the journey to its value may well cause the que tion of real usefulness to be ruised

In particular we may mention two voyages around the world, the latest having been made by a phuble American journalist during the present year, and oc-cupying about five weeks, and the earlier one made eighty years ago, by a young man of twenty-two, and occupying five years. The former traveler had the advantages of the modern high-speed ocean steamship. both on the Atlantic and on the Pacific, besides utiliz ing the trans-Siberian railway, the railroads of Korea and of Japan, and the special efforts of the transcontinental railroads of the United States. The latter made his entire trip in one vessel, the voyage having the original object of carrying Greenwich time to many blands of the sea and thus enabling their precise langitude to be determined; but the voyage of the "Beagle" will always be renaembered because ('harles larwin was on board, and because the fruits of thu trip around the world were the "Voyage of a Naturaland "The Origin of Species."

It is not how rapidly a man travels, but what he sees, and the use he makes of his observations which give the true value. A study of the time tubles of railways and steamship lines would have given all the ratiways and ateamsing lines would have given all the information which the later of these two journeys bus thus far produced; while the consequences of that earlier and more deliberate voyage are continuing, in on ever-growing magnifude for the unlightenment of

### Harmsworth Trophy Retained by England

THE British motorboat "Maple Leaf IV," owned by I. E. Mackay Edgar and representing the Royal Motorboat trophy, known as the British International Motorboat trophy, known as the Marmaworth Cup, in a series of

races concluded on September 12th, over a course in Osborne Bay, 1ste of Wight. The "Maple Leaf" won two out of three races, and thus retained for Great Britain the trophy which she wen on Huntington Bay, ortion the (ropin) which she wen on functington (op), Loug behalf, hist vear. America was represented by the "Ankle Deep." She fullshed second. If, Holling-world's "Crimather," a British entry, was third. The curse measured 324 multied inlies. If was covered by the "Mayle Leaf" IV. In a funding and 10.25 sec-onds, by the "Aukle Deep" for Cambridge and 30-255 mids, and by the "Crimather" in 40 minutes and 30-255

#### The Motor Tank Ship "Hagen

THE trial trip of the new motor tank ship "Hogen" showed some interesting figures as regards fuel consumption. It will be remembered that this first birge mercantile motor vessel (2 evele motors) built at the Krupp Germiols yard at Klel is one of three vessels contracted by the German-American petroleum com-pmy. Two are sister ships of 8,350 tons dead weight capacity and 3,000 brake horse-power, while the third will have 15,000 tons capacity and 4,000 horse-power The "Hagen" is one of the smaller vessels, 100 feet lu length, 53 feet breadth and 32 feet 4 luches depth to upper deck, belog a twin-screw ship with two 6 cylinupper nees, neigh is twisterew stip win two reyni-der sets of englines of 1,500 horse-power each. The delivery trip-rounding life Skaw and in the North Sea-took place from March 15th to 10th, and mensur-ments showed the oll-consumption of the main engines at 1,050 brake horse-power (1,500 indicated horse-power) to be only 0.424 pounds fuel per brake horse-powerbour (0.297 pounds per indicated horse-power), including the fuel consumption of one of the n for injection all. In spite of liberal lubrication on this first sen stilp, not more than 13 pounds of inbrickling oil per hour were used for the whole engine plant, and on per nour were used not now whole engine paint, and in the future this will naturally be decreased. With 2,100 hrake horse power total, the ship attained 11 hones, and at 2,700 horse-power (3,800 indicated horse-power) it hereased to 12½ knots. As for as is known, every) Intereses to 1223 known. As far as a sanch, deepele martine engines of equal power barn 0.32 pounds per indicated horse power (the "Hugen," as above uses 0.297 pounds). Thus the drawback of increased con-sumption till now booked upon as uscolated with 2-cycle engines did not occur in the 'Hagen," and the great advantages of the 2-cycle engines over 4-cycle dld not have to be paid for in extra fuel,

### The E. H. Harriman Memorial Gold Medal

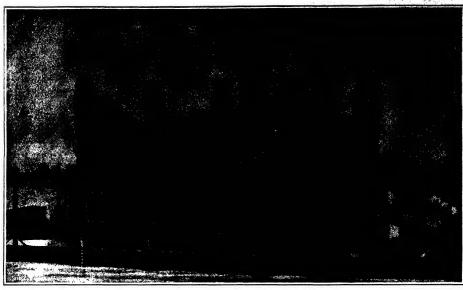

TO create a better understanding on the part of the public in what the ridironds are doing to make safer conditions of travel and to sufeguard their own personnel, through the prevention of accidents, Mrs. E. H. Harriman has offered a gold medal manually, to be awarded by the American Museum of Sufety

In amounting the gift, Mrs. Hutraman shites "To stimulate a direct effort for the conservation of human life, it gives me pleasure to place at your disposal the U 11 Harriman Memorial founded by me, to be awarded annually by your board to the American steam rullway making the best record in accident prevention and industrial hygiene affeeting the public and its own personnel thirting each curren

The gold medal will be awarded to the railroad com-pany liself, a replica in silver to the member of the operating department of that road who has done the most to ladig this condition about, and a replica in bronze to the employee of the winning road who was most conspicuous in the promotion of safety by sug gestions or otherwise

### The Current Supplement

A N important article in this week's issue of the Scientific American Supplement, entitled theters Patent in Relation to Modero Industrial Conditions," comes from the pen of F. B. Fish, one of the foremost putent lawyers in this country.—II. E. Ives and M Lucklesch have investigated the distribution of luminosity in nature. Their report appears in this week's SUPPLEMENT—MY T II Doubt contributes a handsomely illustrated article on the White Marble minuspacely instructed arrive on the wants auronal Temples of Illiwara, the exquisite carving of which equals anything that the western world can show—Some thue ugo Prof. Hole of the M. Wilson Solar Observatory Investigated the magnetic field of sumaposts. More recently be completed a similar study of the much weaker general magnetic field of the sun as a whole. This brilliant layestigation, in which use is made of the fact that a magnetic field produces certain iditeration in the lines of the spectrum, is of interest not only in its relation to the san but also on account of the light which it sheds on the probable cause of terrestrial magnetism -- Sir Officer Lodge's address is concluded in this issue, its closing paragraphs devoted to asvehical research and the question of the nevated to psychical resource and the question of the survival of the soul after death, a subject on which the great English physicist holds original views, as our readers know.

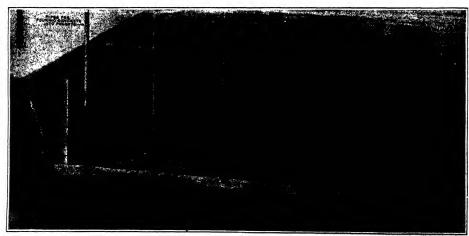

The "tremie scow" with which concrete is deposited on the tunnel.

IN the Science of March 20th, 1913, we total how the four-track tunnel of the Leatington Avenue subway was to be constructed under the Hardman River, and Hindersted the article with drawings and photographs of the Detroit Biver tunnel, which was built in a very similar manner. It was thought then that the work would soon be under way, but It was delayed owing to inability to obtain the steel for the tubes. Now that the actual laying of the tubes is in progress and one of the sections has been sunk, a degend of the interesting so term of tunnelling may not reduced to the contract of t

It will be recalled that the general method of procedure is to dredge a trench across the bed of the river, and in this lay the four lubes of the tunnel, afterward covering them with concrete and then fitting them also with a illing of concrete. The total length of the tunnel will be 1.0% feet, and it will be laid in five sections, four 220 feet long and one 200 feet One of the 228foot sections has now been laid, and is being concreted. The tubes as shown in the accompanying illustrations are flat at their contiguous sides and are connected by transverse plates or disphragms of quarter inch steel which hold the tubes in right relation to one another while they are being sunk, and also provide the necessary steel reinforcement for the concrete that is to be laid over them. The disphragms project well beyond the tubes, and join the timber adde walls that inclose each section. The disphragms are placed 15½ feet apart, and between them pockets are formed in which the concrete will be laid

To prepare a temporary foundation for the section just saik, bents, consisting of pairs of piles connected across the top with a head-piece of channel steel, were sunk in the truchi intendy dredged across the bed of the river. Each bent was carried down to the exact grade by menus of two pile drivers. Five heats were sunk at each end of the section They projected a fool or two above the bottom of the trench, and served merely as a temporary support. The material at the bottom of the trench is very closely packed gravel which forms an excellent foundation for the tunnel.

The four-tube section was assembled on a staging about a mile from the site of the tunnel. When the section had been completed, and it was ready to be sunk, a series of long narrow scous was introduced between the longitudinal rows of piling of which the stuging consisted. As the tide rose, the scows lifeting consisted. As the tide rose, the scows lifeting the section off the piling, and it was then towed out into stream. At one end of the tube section the ends of the tubes were closed by means of substantial bulk-hands which were closed by the control of the tunnel is being lined with concrete section only the two outer tubes were fitted with bulkheads, which were lighter because they were to be used only to prevent ton rapid

Laying a hed of concrete under the tunnel section before removing the buoyancy cylinders. Note that the mouths of the treatie pipes extend below the surface of the concrete laid.

socialize of the table. The finner two tubes were provided with partial bulkheade to beep out the water while the tunnel section was being towed to position. After the section had been floated off the pilling, the soows were suttled, leaving the tunnel section afost. The floating structure was then towed down to the size of the tunnel. It was decided to start sinking the sections at the middle of the river rather than at the shore onds. Balf of the river was encortingly blooked to navigation and piles were driven between which the tunnel section was guided and securately centred.

When the first section of the Petroit River tunnel was sunk it plunged endwise instead of settling down evently. Secured to the top of the tunnel were four buoyancy cylinders, two at each end, adapted to support the tunnel section after it had lost its buoyancy, but as there were no parti-

tions dividing the tub slight tilt was accentuated by a rush of water toward the toward end. To be sure it righted itself immediately after it had plunged far th to submerge the buoy-cylinders, but there was ancy cyli danger of straining the contion. To overcome any such tendency in the Harlem tunnels, the section wa provided near the heavier end with partial bulkheads tending halfway down from the upper part of two of the tubes. As the tubes filled with water, the heavier end tipped downward until the lower edge of the partial buikheads touched the water. Then the air trapped back of these bulkheads buoyed up that end until the tunnel sec The trapped air was allowed In escape through hose run-ning to one of the barges, where it was controlled so as to keep the section on an even keel When the tunnel section had been sunk to within about a foot of the top, it lost its buoyancy and sank abruptly until the buoyancy cylinders strapped across end came into contact with end came into contact with the water. These intoyancy cylinders were each provided with a central chamber into which water was admitted, until the tunnel section sank beneath the surface. derricks then took the strain. which amounted to about five tons altogether, and lowered the section slowly until rested upon the bents. The section was fitted with four masts, each bearing a target, so that by means of level and transit it could be brought into accurate alignment with the line of the tunnel. This was done with extreme accur acy, and the tunnel section, heavy as it is, is not more than 1/4 of an inch out of the true position

The method of laying the concrete under water was fully described in the laye of March 29. A large scow fitted with concrete mixing machinery is provided with five tow-

Market also all the to

ers so speced that when the scow is brought into position transversely ever the tunical section, "transies" may be lowered from them between and at each side of the funnel tubes. The tremise are provided at their upper ends with hospers adapted to receive liquid concrete. The first charge of concrete is relatively day and is adapted to force out the water in the pipes. Thereafter the concrete dropped into the pipes is quite liquid. The ends of the transies project below the surface of the concrete already deposited so that the latter will form a cover to exclude the water. As fresh concrete is added this cover will foat and protect the fresh concrete from the settion of the water. This system was employed in laying a concrete bed for the tunnel section after it was such that each of the disphragms would support its share of the load. The busyaner, cylinders were then revoved, and at the present writing the work of filling wavel, and at the present writing the work of filling wavel, and as the present writing the work of filling

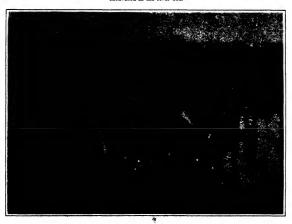

the peckets with concrete is nearing completion. When the next section of the tunnel is sunk, it will be connected to the present section by means of divers. When all are sections of the tunnel have been laid and concreted, builkands will be built around the ends of the tunnel and the water will be pumped out to permit of connecting them with the land section of the subwer We are indebted to Mr. Olaf Hoff, the inventor of

We are indebted to Mr. Olaf Hoff, the inventor of this system of tunnel construction, for the accompanying photographs.

### Bringing the Sea to Miraflores Locks

O<sup>N</sup> the morning of the last day of August, this year, the detonation of 38,000 pounds of 45 and 60 per cent dynamite opened a breach in a rock-and-earth

Towing the first section of the new Harlem subway tunnel to position over the trench previously excavated in the river bed.

The tunnel section filling with water and slowly sinking. Note the four masts bearing level and transit targets.

fill which had been made across the prism of the Panama cansi about a mile from Miratiores locks, and completed the eight miles of sea-level canal from Miratiores to the Pacific.

The duty of this dike was to exclude the water of the completed portion of the canal from the huge-execution in which the concrete masonry of the Minnestow took was being laid. The dike size rendered it possible, without having to wait for the completion of the locks, to complete the sex-level approach to the canal down to the full depth of 45 feet, by means of the excommical floating dredges. The dam was thrown across the canni prism some fore thousand feet to the south of the locks, and this stretch of a mile or so was executed in the dry by steam showels. The Mintafores locks are completed and the gates have been hung in position; so that there was nothing to prevent the

canai builders from permitting the Pacific Ocean to ebb and flow right up to the entrance gates at the seaward end of the locks.

In preparing for the blast, 541 three-inch holes were delibed vertically into the dam to an average depth of 30 feet, and the 18 tons of dynamite was distributed among them. The conditions at the time of and after the explosion are very lucibly described in the current issue of the Canal Record—a Government weekly publication issued under the editorship of Mr. Bucklin Blabop, which, during the building of the canal, has most admirably fuffilled its purpose of keeping the general public in touch with the progress of the construction of the great work.

At the time of the explosion, the water in the channel south of the barrier was nearly at low tide. The

dynamite tore a gap in the dike about 100 feet in width; but as the bottom of this rent as still at some height above the existing tide level, no water passed through At about half past one on the same day, however, the water in the sea-level channel had risen nearly to the top of the A man with a shovel dam. then opened a small treach ss the dike, through which a slight stream of water began to flow l'inder the cutting action of the water, the opening rapidly increase in size, until, some forty minutes later, a great torrent of water was poming through an opening 30 feet wide, with a fall of some 30 to 35 feet The rush of water, says the Record, ate uwn; the sides of the opening stendily, carrying large sections of the dike. including the trestle from which the dike had been built, together with other débris. into the excavated section of the canal between the dike and Miraflores locks The pit was filled rapidly, and at 3 o'clock, or one hour and twen-ty-five minutes after the first small strenm was opened by the workman's shovel, the level in the inside channel was the same as that of the outside commel, the gap meanwhile buying been opened to 400 feet of more

Two diredges are most at work on opposite sides of the dike removing wint is tell of It, and by October 1st 1 is expected that there ships will be able to steam up through the Paritie and of the canal for a distance of eight and one half milles to the locks As a matter of historic lates est, our readers may like to know that the hanner "this dean" was the first vessel to pass through this section of the canal made for isown steam, which it did on Theoday after noon, September 2nd.

Of our two illustrations, one shows the mass of débris in the air and failing into the water a few seconds after the explosion; the other, taken later, is a view tooking from the seaward end of the Miraffores locks and showing

the tidal waters of the Pacific tiling the approaches

### Handy Vise Tool By I. B. Spittel

Folls small work that cannot be hold in the vice halone the tool fluestrated in the accompaning drawing will be found very convenient. It consists of two pieces of cold rolled sixed,  $\lambda_0$  the barner by 4 inches long, connected at sectic end by serrows which are threaded into one of the pieces and shife freely in the other. They are also connected by strips secured there to with flathend servess. At one end the servers suffringle slots in the strap to permit of a limited amount of movement of the two pieces of steel toward and away from each other. The strap projects beyond the edges of the steel pieces, so that when the tool is pinced in the day, the predicting ends will rest an its just of the vice pieces, so that when the tool is placed in the day, the predicting ends will rest an its just of the vice in sistence of the vice pieces is a block of furnificial ends of framed with a toothed V groove to grly round surfaces readily for each of the connecting screws is a cell spring adapted to spread the members upart. The work may be temporarily held to the tool by declaring the blocks or faves on it and champling them to the therefore the tests and the vice just and be tightened to grly the work may scrutch.

### Oxidized Carbon Plate

By "Delta"

F is earlien plate, or preferably a number of carbon I plates arranged in sortes in a set of cells with lend cylinders for the negative terminals, and a mixture of one part sulphuric acid to eight parts of water for the electrolyte, be subjected to a current of ten or umperes, hydrogen gas will be given off conjonsly from the lend cylinders, while the oxygen that is generated will become absorbed and possibly partly combined with the curbon plate. It is best to arrange the cylinders of sheet lend with lenden hooks bent over the upper edge of the vessel, and supporting the cylinders so that there is a clearance of about an tach from the boltom of the cells. The cells should be tilled to within about un inch of the top with the dlinte sulphurle acid the curbon plates have been charged for about (went) minutes, they should be dipped into hel water to free them of any acid remaining, and then should be dried tipon an examination, it will be found that the colo earbou plate has become changed from the usual graphite color to a coffee brown all through that part that has been submitted to electrolyte action. If a test be made of the carbon in a bullery, it will be found that the cell is far more powerful in its action than with untreated carbon. The porous cup as well as the perovide of manganese and grammated earbon, which is used multily as a depolarizer, may now be dispensed with, and hence the internal resistance of cell will be lowered considerably. As the carbon surface has been roughened by the electrolytic action surrace has been roughened by the electrolytic uclina, not only be the negative surface hiereneed, but the tendency of the free hydrogen to cling to the surface is overcome, for the oxygen of the oxidized plate combines with the hydrogen to form water. Cells with curbon plates treated as described have been found of use for intermittent service as, for instance, in the intterles of electric cells and nickel-in-the-slot muchines, where the vigor of the cell is so improved that the number of cells in the battery may be reduced

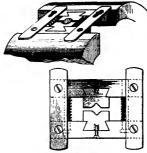

If n dozen carbone be treated in series as shown the Illustration, it will be found, upon disconnecting the carrent, the cells form a powerful storage latticey, enjudie of giving in considerable amount of energy in terms. This was discovered by the author when oxidizing a set of carbons for dry

### An Electrolytic Rectifier for the Garage

THE chemoed and simpled cherric lighting system for the automobile to day by the artificial form of the automobile to day by the straight battery system, in which a storage hattery is carried on the runting board or under the sent of the ear, and is connected to the head side, and tall lights lirrough switches on the dash

Such a battery, which is usually of 80 or 100 ampere-hour capacity, must be charged reguhirly from some source of power.

If the owner of such a system has a (10-voil ullernating curreal circuit in the garage, or has access to such a circuit, the following rectifier, which may be constructed for 'un expenditure

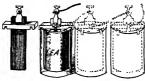

Tool for holding small work.

of a few dollars, will enable him to charge his lighting or ignition battery from such a source

or agricum enterly from such a source.

The first and most difficult part of the set to construct is the transformer. The core of this consists of a standard ten or twelve point off off No. 2B. W. G. soft from wire. This coil is first soaked thoroughly with shelles, care being taken to see that all binding wires or wires which run at right angles to the main canonicous of the coil are removed. This is to cut down eddy current loss. The coil is then phiesed in the over of a store and settle heat applied until the sheline is saked hard. The coil is then taped with three layers of half-inch pain cution take, wrapped spirally for about two littles the circumference of the coil. This twee is then while the late of the circumference of the coil. This twee is the relative of the circumference of the coil.

Arrangement of cells for oxidizing carbons.

Upon this laped ever the primary winding is now wound. This condusts of eight hundred turns of No. 22. B & S. double cotton covered wire, from two to two and a haif pounds being required. This should be put on in four layers of two hundred terms each. Each layer should receive a cost of sheline and a covering of one layer of the cotton lape. In winding the transformer, the trou wire core should be changed in an uprifult position on the edge of the work bench, so that the spool of wire may be passed through the center and over the outside without difficulty. Care should be taken when purchashing the wire for the transformer to see that the spool of whom the center of the row where coil. It

will be found that the ordinary these and deposits on a pool will do this without any disconsity. Ours showed be taken in the winding operation, to see their turns or wire its closely adjacent to each other on the inside of the coil and are speced apart on the outside in order to compensate for the difference between the interior and exterior disconsists of the own.

When the primary has been completed, the ends should be soldered to two short plees of finished and cord for terminals, and the whole wisding covered with three layers of the ection tape. The transformer at this stage should receive another cost of shellen and a second baking, care being taken to see that the ecoli does not become hot enough to burn the installation.

The secondary winding is now organized in these afferedly over the primary. The words of the property of the p

The next interest the country to be constructed in the rectifier itself. The parts meeded or it are as follows: rectifier itself. The parts meeded for its are as follows: Two enames were buckets of about two gallons caspedly each, four pieces of sheet true, five lucius wide by six inches long; two pieces of 1/16 inch atuminatum, three tuckes wide by seven inches long, and two pieces of hard wood strip about one quarter inch thick, one half inch wide, and two feet long. The true pistes should have holes drilled or punched in the upper corners of each pair, and the atuminum pieces should have a single hole drilled in the indidde of the top edge to receive a binding post or bross matchine levit and unit.

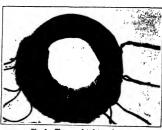

The two strips of wood are isld logether with the vo abundance plates between them, spaced about sixteen locks, center to center. An iron plate is then placed on the outside of such wooden strip, discussion propells an abundance and the strips to resister with the holes in the from plates, and the whole boiled longether with the from plates, and the whole boiled longether with larses unechine boils hiserted in these holes. This portion of the rectifier may be seen in Fig. 2, resiling across the tales of the two palls. This figure shows the complete rectifier in use charring a 10 sampershour lighting latter). Two pounds of soddium phosphate is placed in each

Two purposes of sodium phosphate is placed in each pail, and the pails are their filled with warm water. After this cools, the reclifier may be connected up as shown in Fig. 3. In the figure 4 is a double pole two ampere fuse block to which the 110-voit circuit is connected. B is the transformer, the two windings

being shown on different parts of the core for clearness. CC are the wo rectifying cells, and D is a double pole six ampere fune libeck to protect the lattery which is shown at E. The positive pole of the lattery should be connected to the middle tap of the secondary winding, and the negative pole should be connected to the rion electrodes of el to the iron electrodes of the rectifier. The outside terminals of the secondary lead to the two

It will be found that a rectifer constructed according to these directions will charge a state of about two to two and a hair amperes, while drawing about three quarters of an ampere from the fline. When the rectifer is not belug used, the plates should be lifted from the solution. The plates should also be cleaned frequently and the solution renewed every few months. The just of work renewal will be indicated by the heading of the solution. The shad of work renewal will be indicated by the heading of the solution. The shad of work renewal will be widely and the solution of the shadow of the shadow.

### Fredericis Against Bank Note "Raining" and Forgeries

N ingenious device for imparting security to bank a noise and other security documents and means for detecting attempted forgeries, has been invented by Airred E. Hawtree, an English electro-chemical engineer.

Mr. Eswiree has used as a basis for his invention the well-known principle of the sound waves of the phonograph record. For instance, he manufactures the paper upon which a bank note is to be printed with

one or more edges of tregular, but predetermined form, such form corresponding to certain sound waves. For a strepound note the edges record the spaces words "fire peutids," and when piaced in the reproducer the note piainipsed in the reproducer the note piainly smootness its rightful denomination. It have been been been assumed to be almost absolute protection against "rainbank notes or checks, since a noteration in the proposed of the piace and the proposed of the proposed of the piace and the piace of the piace and the piace an

The method of preparing the bank invested upon gians, by a stylus which sired upon gians, by a stylus which is connected to a diaphragm, the sixter being caused to vibrate with the desired sounds. An enlarged photoarspinic cupy of this line is next made, and by hand or by a photo-mechanical process a thic template is cut of the

same emisrged form. This template guides a tool which curs out the same form to the required scale in the form of a steel cutting knife. This knife is employed for giving the edge of the paper the required outline.

The device for use in reproducing the sounds thus recorded by the paper's adon. M. Bastrose describes as a pair of vertical cylinders rolling against each other and operated by a suitable driving power to rotate and operated by a suitable driving power to rotate and operated by a suitable driving power to rotate and operated by a suitable driving power to rotate and operated by a suitable driving power to rotate and operated by a suitable driving a hole in it under the line atomy which the cylinders to consult has, similar to some form of these in general use upon talking machines, is placed beneath the parent above described, and a suitably shapled stylin projects upward through the hole mentioned. The document to be tested should be held vertically with the sign under samination resting on the plane. It should be advanced until the rotating cylinders engage fix vertical edge. They should then draw it between them, the roughened lower edge passing across the stylins which projects upward through the hole in the plane. This would cause the stylins to actuate its sattached reproducing parts, when the nature of the sounds entitled owned determine the symultonesses of the document.

The wide possibilities of this device may be readily insighted. A bank employs a clerk whose sole duty might consist of running bank notes through the phonograph, and any of them which did not renty truthfully to their denominations would be repurred an counterfeit. Or timid and suspictous private individuals could install in their homes or offices a machine which would advise them above a vestige of doubt whether their cash in land was genuine or superious. In the filtustration, Fig. 1 shows a general view of

In the fillustration, Fig. 1 shows a general view of the device and Fig. 2 a section of the reproducing end with the horn and part of the strip B removed. Two strips of metal AB are separated by a thin and narrow strip U atong one of the edges, thus forming a deep and narrow channel. ### Improving the Reproduction of Talkingmachine Records

A SIMPLE clarifying, articulating and amplifying sittenthment for talking machines was discovered by the accidental touching of a fine needle with the finger while a record was being played. The inventor, M. B. Claussen, about two years ago, while teelting out assurecords, happened to touch the needle and noticed that it vibrated. He was using a very fine straight-wided needle, which produced a low sweet tous, but lucked

A SANCE OF

A combination measure and funnel with automatic shut-off, designed or the automobile owner or the garage man.

the power lo propel the sound from the horn. This finneedle was free from scratch, and while it did not produce the volume of the heavy beadle, it had none of the heavy needle's mechanical tones. Mr. Clausen argued that if he could add power to the vitiration of this dise needle, it would reproduce all there was in the record with a volume equal to that of a heavy needle without any of the heavy needle's defects, such as excratch and aftertones. Besides, the great wear on the record caused by the heavy needle would be avoided. After trying many devices to increase these

A device which clarifies and amplifies the reproduction of talking machine records.

Muratum, in found that a disk of a certain diameter, hickness and dendity strached to the needle near its point, not only increased the volume of the fine needle considerably, but retained all the purity of the fine needle, and, at the same time, by its vitractory action eliminated the aftertones and caused each word and note to be reproduced clearly and distinctly. Some indistinct records even became andible. Tones never heard before were brought furth. The sound was lifted clear of the machine. The slager or mustein was in the rown, not in the box. It reproduced at the artist

One-ton truck crane with compensating quadrant.

put into the record in the nerbal's natural voice, or with the musician's artistic touch. In the present form the device consists of a disk, two springs and an mostiled metal band. The band is slipped over the circumference of the sound box, and the disk over the point of a fine needle. The springs hold the disk in parts.

Tests, made under a microscope, of records played one thousand times with the device showed no perceptible wear. The long point of the the needle instructed all parts of the record, but had not broken down the well. Further experiments showed that by slightly

hereasing the length of a flue, stratight sided needle, the vibrations were increasest and the reproduction brought to a point of perfection. The device is made to fit this needle, and with it produces the best results

### An Automatic Shut-off Measure

A COMBINATION measure and lunnel, designed primarily for the automobile awner or the garage man, but neefful ulso in many other ways, bus been placed upon the market

As shown in the accompany in tiline and funcing the form of the fo

the or other vessel and, by means of the bull-valve, the flow can be stopped instrutioneously by releasing the pressure on the thumb plate on the upper end of the valve red. The valve is held lightly on his sent by means of a spring.

With this measure, a tank or other receptacle may be filled to any desired height and sinn of without danger of overflowing. On pitching the measure in an upright position after the filling, any liquid remaining in the framed will run back but the measure without dripping on the outside.

### Edison Uses His Old Telegraph Instrument Again

AT the meeting of the old-time Telegrophers' Illatorical Association of the United States at Mounit Clemens, Michigan, on August 28th, Thomas A Eillson sent a message over the wire to President Wilson. The occasion was of special interest, because Mr Eillson stood upon the same site where he stood when he sent its first message as a telegraph operator, and used the same instrument he used lifty-one years ago when, as a boy of fourteen, he sent his first message over the lines of the Grand Trank tallway.

Back In the pre-telegraphic days, when Edison wan only a newspaper boy on the Grand Trank Rathway, he showed his youthful enterprise by printing and selling a small newspaper containing the news along libe route The kept a little font of type in the baggang-sur and quinted the paper on the train, so its leans were strictly into the minute. It was during this period that in Indiaman lifted labu lot the ears, later causing the deafness that now blank bis hearts.

### A New Compensating Quadrant Crane

In an accompanying illustration is shown a new holstting crane, the invention of Cupt. A. P. Landin and Axel Wella, two matthe engineers. Although this crane was first announced about a year ugo, it was not mill

recently that it come into general industrial ness, being maniferrierd in severed different models. The type shown is a one-ton crane with a compensating quadrant fastened at the lower cut of the jib which can be instead of lowered. The quadrant is provided with teeth that engage in a rack and roll in a slot in the horton plate. An actualing series works in heartings in the top ferme. This actuating series whigh the quadrant by mems of a not which slides on a guide at the top of the frame. The bottom plate is provided with four tollers for slewing and each model is so constructed that it will oper attentionals a complete circle. In the settlement, and the supposition of course, the pointed in any direction by montpulating the tracks on which it is mounted.

The compensating quadrant has two functions, the more important being to give the load a hortzontal travel. With a multiple speed, obtained by means of an electric motor and gears, many sized loadcan be adjusted without changing gears

#### A Vehicle Movement Recording Device

A LTHOUGH transportation by motor vehicles has become largely a science thanks to the efforts of efficiency engi neers and others, and routes once covered in a haphazard manner at the discretion of the driver now are plotted and covered according to the well thought out plans of some one who has supervision and who can best visualize the system with a view to promoting its efficiency, the fact re-mains that drivers still are out of sight of, and consequently out of the influence of, their squeriors or whoever may have the good of the service in charge, for a considerable part of their time. That most drivers maintain their schedules un der such circumstances-when the watch-ful eye of the "boss" is abscul-is a tribute to the honesty of the fraternity, though it by no means obscures the fact that other drivers, less houest, do not

scruple to loaf when the occasion presents itself.
It is to check the performulice of these drivers and their vehicles that the justrument shown by accompanying filustration has but recently been brought out. Need-iess to add, the instrument performs valuable service, too, when applied to the vehicles driv men who are known to be perfectly honest with their employers and who adhere rigidly to their

Briefly, the instrument records the thne a hicle has been in motion. the number and duration of the stops made, the uileage iraveled and the speed of the vehicle at any moment it is under way. Despite the multi plicity of its functions however, it is not as complicated us the result achieved would seem to indicate

The record, which is made apon a tape about twice the essent for accuracy, though it may be ap- has so convincingly an extract the common stated. At the profitably to and frowing the produced in part by clockwork, and in part by clockwork, and in part by the movement of the vehicle to which it is attached. The laws extract the profitable profitable that the determining speeds continuingly and the part by the movement of the vehicle to which it is attached. The laws extract the average return, in freight charges, of ½ from a distant point provided that by so be produced in part by clockwork, and easy method of determining speeds court jer too jer mile, the earnings per doing prompt and effective accommodations of the vehicle to which it is attached. The laws the provided provided that by so the part of the vehicle to which it is attached. The tabe is an essential part of the device, of course, and therefore should receive con-sideration first. Its length is sufficient to permit the recording of 36 hours' service It is ruled lengthwise and also transverse-The width of the tape represents a distance traveled of two miles, the sub divisions representing one quarter mile The vertical lines on the tape are the time lines and they represent 15-miu-ute intervals. The tape is wound up on the large dram at the rate of one com plete revolution of the drum every six hours by clockwork. Pressing against the tape there is a tiny pencil or styles which is moved across the width of the tape by can mechanism operated through the ediary of a flexible shaft from one of the front wheels of the vehicle

When the vehicle is stationary, the pencil does not move, but us the tapo is wound up on the drum a straight line corresponding in length to the duration of the stop in minutes, is traced. Immediately the vehicle is set in motion, how ever, the stylus commences its travel back and forth across the tape, and as the ity of the record lines which permits quick and accurate readings of speed to be made. It is possible, of course, to di vide the mileage as indicated by the trave of the penell across the tape into the the made and onick work is essential a de vice similar to that shown by one of the

In use, the record tape is placed be neath the transparent portion of the device, as shown by the picture, and when any of the record lines is placed directly beneath the hair-line, the speed of the vehicle for that moment is indicated by duced to an effective average of but the pointer on the scale. Practice is nec-

interval, and in this way to compute the speed, but where many computations are Illustrations is used; it is a convenience that has been developed for the quick reading of many tapes such as would come from the instruments on a fleet of ve hieles, though it is not absolutely neces sary and may be dispensed with as ex-plained above.

Examining the "log" of the truck.

hicle some hours after the occurrence of an accident will serve to make plain its undoubted advantage. Witnesses of the accident in question—it is a matter of court record—declared that a heavy commercial vehicle which killed a young lad in rounding a corner, was traveling in excess of 20 miles an hour and one went se far as to state the speed was nearer to 30 miles an hour. Examination of the record tape, however, served to demon strate beyond cavil that at no time during the previous 12 hours had the speed of the vehicle exceeded 12 miles an hour, and that at the time of the accident it

In another illustration there is shown the method of removing the record tanethe instruments after each day's from the instruments after each day's to be desired, yet, when investigation work is complete. As the operator works shows that an average of three hours per outly at night and as the illumination of garages is not always as brilliant acould mixed, the motor truck becomes unprofibe desired, he carries a miner's imm af-is able for relirond service. Their added fixed to his cap and operated by a small capacity and increased speed are storage battery hooked to the back of discounted by aget fidel times. As the has been of the truck that are attacked in the capacity of the storage batter to be a some fixed to the contract of the capacity of the capac movement of the tape is constant, the line a beam of light upon the tape and exam-traced by the stylin is at an angle to the ine readily the "log" of the truck.

### Terminal

THE RESERVE OF THE PROPERTY OF

By Robert L. Niles

WHEN it is reflected that no railroad, steamship line, canal, towboat service, trolley line, or ateamboat, as to the freight carried, begins at the beginning or ends at the end, that is to say, that d thus transported has had to very pour be collected, and will have to be ultimate be collected, and will have to be ultimate-ity distributed, by some other method, by horse haulage or manual labor, the vol-ume of such collection and distribution and the importance of the problem bee most impressive

The most serious difficulty the rallros are called upon to solve is the question of terminal facilities. The freight car, which, once upon its journey, may readily cover some 250 miles per day, is, at present, by the congestion of terminals, re

The recording drum

Device for measuring angles on the tape.

\$31.25 per day to an actual \$2.50 per day
—a figure at which profitable operation becomes well uigh impossible. The anomaly is presented that the larger a city s profitable its freight tonnage in proportion.

The manifest solution for such conditions is, if possible, au enlargement of terminal facilities Cortailment of earning power to the railroad is not the only result of congested terminals, it involve heavy additional and unnecessary expense to each individual shipper, and to all stevedores and teamsters, and proves greatest obstacle to the employment of otor trucks in the collection and distri bution of railroad freight.

From the standpoint of the general pub-lic, its health and convenience, the elim inution of horse-drawn vehicles is greatly to be desired, yet, when investigation pers runs as high as 50 cents to \$1 a ton any fraction of the total thus rempred, and over per mile, or to one hundred to from the congested zone would in every

vertical time lines, and it is this angular | The Motor Truck and the Freight | two hundred times as much as the mile age charge of the railroad, so that, save for distant points, the haulage charge in greater than the railroad charge. To refired, short hauls in the consested dis-

> In the interests of both the railroads and the shippers it is evident that some plan should be sought by which these de-4 inys may be avoided or diminished. expressed heretofore, the natural solut would be the expansion of present task age and platform space, as well as age ann piatrorm space, as well as the approaches thereto, yet extensions of present sites would involve staggering expense, and an increase therefore of capitalization difficult, if not impossible, to

There remains, therefore, the alternative of the establishment at other and dif-ferent localities, of supplemental receiv-ing and delivery stations, where such needed trackage and space either at pres-

ent exists or may be cheaply acquired.

Such a solution, how ever, would necessitate much longer ladividual haulage, which in the case of horse-drawn vehicles would seriously de tract from the advantages of the prompt ser-vice thereby secured. It is here that the motor truck appears to its best advantage. With its in-creased speed and carrying capacity, and ability for continuous, threiess service, regardless of length of time in operation, a comparatively "long haul" becomes less ensome than a comparatively short "wait." With horse equipment a "wait" of an hour is preferable to an additional length of haul of % of a mile. With a motor truck an extra haul of four miles is less expen-sive than a "wait" of one With motor equiphour.

they can succ safully haul trailers: to wit, inexpensive carrying bodies without expensive motor equipment. Such trailloaded, at leisure, and ultimately picked up and dispatched by the motor unit, itself either a load carrier or simply a notor, as conditions warrant

It would appear therefore that through the establishment of such "annex" freight terminals, confined, it well might be, to certain classes of freight, or certain ex-tensive shippers, the congestion of the terminals at present existing would be materially reduced, and it seems not too sanguine to imagine entirely removed, thereby expediting not only such tonnage as was therein handled, but that still distributed from original depots. Such service might well do for the various rail-roads what the New York Clearing House has done for its associated members, and expedite and inbricate the whole problem of freight handling. Manifestly it would not be necessary for such a system to at-tempt to handle even a substantial part

of the whole tennage.

### **Motor Truck Queries**

M. O. L. writes: "In my grocery delivers wagons for regular deliveries and a 2-ton truck for hauling my goods from the rallroad to the store not some light vehicle which I can use for 'special deliveries' to give prompt service to customers after the regular de-

Hivery has been made?"

A. It is not to be expected that a delivery wagon used under these conditions would be run at nearly full load. In fact. nine times out of ten you would probably not have occasion to carry more than one lundred nounds—and much less than this in many instances. These are conditions under which a motor truck cannot be made to show a maximum return on its investment, but us a convenience to patrons and an advertisement, it would soon prove its value. What you need is a speedy, 500-pound vehicle that is easily handled and that can travel 35 or 40 mile on a gallon of gasoline There will not then be such a discrepancy b rated capacity and the normal loads it will be called upon to carry, and the co per delivery will thus be kept down. It would seem that a three-wheeled "motor-cycle track" would well answer your re-quirements. Such a vehicle can be ob-tained at prices in the neighborhood of tained at prices in the neignormous 48400, and can carry londs of 600 pounds and over. The regular motorcycle with sidecar delivery van can be bought for about \$330. This has a capacity of 400 pounds and, like the one mentioned above. ls no more difficult or expensive to operate than is a motorcycle.

J. H. O. writes "I have a large barn which I wish to convert into a garage for my delivery tracks, now stored in a public establishment I have alternating electric current in this barn, and would like to know if there is any manner in which I can convert this into the direct current for charging electric vehicles.

A. You will need what is known as a "rectifier." These are made in several different sizes and styles, and it will be necessary for us to know the voltage and number of cycles of your alternating cur-rent, and the number of batteries you will need to charge, together with their charging rate. The smallest instrument suitable for charging a single electric com-mercial vehicle at 30 amperes costs in the mercial venicle at 30 amperes costs in true neighborhood of \$200. Of course this rec-tifier can be used for an indefinite length of time, and thus several vehicles may be charged in succession. To charge more than use set of cells at, a time, however, you will need a larger outpt.

### An Eleven Year Old G. V. Electric and a Millionaire Driver

This 1-ton G. V. Electric went to work first in Troy, New York (November 13th, 1902) and then emigrated to Worcester, Mass., where it has served the Coes Wrench Company for some nine years. Is driver, pro tem, is Mr. F. L. Coes Ismaell. Mr. Coes is very proud of his veteran electric.

This truck is one of several bundled G.V. Electrics still in service after from 6 to 11 years' work. The contrast between this 1901 model and the 1913 G.V. product is tremendous, but—it to the envioble performance second of these early types, plus the greater relative efficiency of the modern G.V. which brings us our commonsus business

We have over 3000 G. V. Electrics in service and are trebling production facilit. Write for catalogue 101 and information about our new and exclusive refinements

### GENERAL VEHICLE COMPANY. INC. General Office and Factory Long Island City, N. Y.

Va. writes: "We operate five 8-he Va. writes: "We operate aw 3-horse trucks in our coal basiness, but want to motorize our delivery equipment as soon as possible. These heavy trucks represent a considerable investment, however, and as some are provided with modern elevating bodies, and others with the latest type of side chuics, we are naxions to know if these can be mounted on a motor reacher frame—and thus save a portion of and thus save a portion of truck fram the cost of the installation."

A. Not only will 3 on he able to use the original truck bodies, but the rear wheels power, you will not need to "scrap" any of your old truck equipment except the front wheels. When these are removed, the front of the truck is placed on the "fifth wheel" provided for the purpose on the rear of the platform of the tractor, and the old body and rear wheels thus serve as a trailer. By the use of such a tractor, the capacity of the original bodies is at least doubled, inasmuch as twice the number of trips can be made, or the same number of deliveries can be carried a greater distance. By means of the prope rigging, the bodies may be easily reor set in place on the tractor, and thus one body may be loaded while the other is being run to its destination. The operation of a tractor and trailer is not difficuit, even in congested traffic, although of course the vehicles could be run only a short distance on the reverse

B. E. M. asks. "Why is the fixed spark' used to a greater extent on trucks than on pleasure cars? What are its advantages?

We do not know for certain that the fixed spark is used to a greater exten mercial trucks than on pleasur There was a time when the fixed spark was popular with taxical man turers, but while these machines are list ed under the head of commercial vehicles they could hardly be classed as trucks The fixed spark has been applied to some pleasure cars in the effort to simplify the control of the vehicle, and it is this same desire on the part of manufacturers that, at certain times, has made it seem a popu iar design on trucks. The fixed sp renders a motor car more nearly "fool renders a motor car more nearly "root proof," but does not allow of that regula-tion of ignition that is necessary for effi-cient running at all speeds. On the as-sumption that the motor truck driver either is not as intelligent or will not exercise the same care as the owner of a pleasure car, some truck manufacturer ve set the spark to occur at the of the compression stroke and have the eliminated ail means for changing it This is the position which is not liable to produce a back-kick at the starting crank, and yet one which gives good results at ordinary speeds of the engine At high engine speeds, it is advisable to set the spark to occur before the upper dead center of the compression stroke is reached. Improper regulation of the spark, however, may be more harmful than a constant position, and the personal equation is therefore the determining factor as to the advisability of the set or variable spark.

A. I. P. asks: "Why are not more self starters to be found on motor trucks?"

A. The motor truck is a business nece sity, not a iuxnry, and every cent spen on it must show its proper return Furthermore, the number of pleasure carin use at present far exceeds the trucks and designers have therefore turned their attention to applying the starters to what would seem to be the more profitable field. The automatic starter is still a new-conser to the automobile field, and has not been in use on the majority of cars more than in use on the majority of cars more than two years. The time is not far distant, however, when the trucks will be provided with this "inxury," and owners will find that it will pay for itself in a short time. The driver of a truck provided with an automatic starts will be more with an automatic starts will be more liable to stop his sagine such time the vehicle is brought to a hat, say the gains line avent in one year will be coordinately.

# The New Argentine Dreadnought "Rivadavia"

The First Dreadnought to be Built in American Yards for a Foreign Power

THERE is a decided prestige attaching to records for high speed which renders the recent speed trials of the "Biradavia" very gratifying to the builders and ewpers of that ship. The "Biradavia" and her sister the "Moreno" are two dreadnoughts of the largest size and power, for which, a few years ago, the Argentine government solicited bids from the leading shipyards of the world. There was very spirited competition to at the word. There was very spirited competition to secure this contract, and it was a mather of great satis-faction when an American company, the Fore River Ship and Engine Fuilding Company of Quincy, Mass., secured the contract for both ships at a price of \$22-00,000. One of these, the "Rivadavia," was laid down at Quincy; the other was sublet to the New York Ship-building Company Canden, New Jersey.

at Quincy; the other was sublet to the New York Ship-building Company, Camden, New Jersey.

The "Rivedavia" underwent her high speed trials on September 10th, when she alightly accessed her con-tract requirement of 225 knots an hour, the displace-ment of the ship at the time being 27,000 toos, and the average hore-power developed being 40,000. The "Rivedavia" is thus the funites testleship to built in America. Of the dreadpoughts built for our Navy, the "Delaware" made 21,500 knots; the "Utah," 21,01 knots; the "Morth Deloton," 23,01 knots; and the "New York" and the "Tenad" made 21,500 knots. and the "Texas" made 21 knots.

and the "Texas" made 21 knots.

As will be seen from our litustration, the "Rivadavia" differe considerably in her outboard public from the situs of the United States Navy. She has only one lattice man carrying a Street outboard public from the situs of the United States Navy. She has only one lattice man carrying a Street outboard on the output of the older type. The bolise rooms are speed wide spars, the foreward shubbeards he had present the spars, the foreward shubbeards he had been should be shared the state that the sta

guns superposed above the forward turret, and amidships, between the smokestacks, are two more turrets placed as cohelos, and so arranged that the four guns of these turrets can be fired dead ahead, dead astern, or over a restricted are on either beam. The other two currets are placed astern of the mainmasst, one at the after end of the superstructure, and the other on the quarter deck. This arrangement provides for a fire dead sheed or dead satern of eight guns, while the whole battery of twelve guns may be fired on each

broadence.

The armor distribution is as follows: The main belt, 12 inches in thickness, extends for 250 feet amidships; it tapers from that thickness to 5 inches at the bow and 4 inches at the stern. This belt is 9% feet wide and 5 feet of it extends below the mean waterline. Above this belt is a secondary belt which varies from 9 inches in thickness at its junction with the main boit to 6 inches abreast of the 6-inch gun battery. This battery is located between number gun sactery. The battery is located between number is and number 5 turrets, there being six guns on each broadside. It should be mentioned that the "Rivadavia" carries also sixteen édoch guns.

Special attention has been paid to the protection of

the ship against underwater damage. She the any against underwater cannage. She carries tor-pedo net, and, as an internal protection against tor-pedoes, she is provided with a 2-inch interior wall of special steel, and also a 1½-inch deck which is worked auddehips over the double bottom. The ship has a cruising radius of 7,000 miles at 18 knots and 11,000 miles at 11 knots-certainly a most axce

#### Garron' Flight Across the Mediterranean

On September 23rd Robins G. Gerros, the function of Nagatime 23rd Robins G. Gerros, the function of Franch aviator, make what may well be regarded as the most perfused over sea serial voyage in an aeroplane thus fur achieved. He sew across the Meditermean Sea from San Raphes, France, to Biserta, Tunia, a distance of 500 finites. This is the longest over-water fifth ever missed in an aeroplane. The distance was covered to seem flower and fifty-three ministes at the returning seasof of 61-65 miles and hour.

Thus to not the diest that Gaires has crossed the

A STATE OF THE STA

Mediterraneau. In 1912 he crossed that Sea between Tunis and Sicily—a distance of only 100 miles. That performance was much applauded at the time. His new achievement is all the more remarkable because he did not accept the use of torpedo boats to pick him up in case of an accident.

#### Artificial Ment

A COORDING to the Paris daily journals a Belgian scientist, M. Effront, has succeeded in producing artificial meat, and this is another advance made modern chemistry, after the synthesis of regetable extracts or perfumes and even the albumens which are the base of living substance. M. Effront now uses a remarkable process for industrial preparation of nitrogenous foods at a very low price, and these are said to resemble ordinary meat in a striking degree. He uses different residues of manufactures which are almost worthless, such as brewery or distillery refuse products, and from these he extracts a food albumen The refuse material is first washed, then pressed and treated by sulphuric acid and afterward by lime, being then put through other operations which are too long to enumerate, ending by filtering and evaporating in tacso. The result is a pastry extract which has a very pronounced taste of mest and has three times the food. value of the latter, owing to its concentrated state. els several doctors have already me de experiments upon nutrition of the human body, and the results are upon nutrition of the numan body, and the results are quite conclusive. The same chemist produces a like food by the use of fodder, such as hay or clover as the raw material, and this product has a similar nutritive value as has been proved by various tests. Such researches are as yet far from the absolute synthesis which Berthelot predicted, but economists already forsee that the practical use of these nitrogenous products can't me practical use of these nitrogenous products may so far to counteract the continuant rise in priese of food at the present time. Perhaps the day is not distant when science will be able to produce from the mineral world not only foods of animal origin, but these which come from the vegetable kingdom. We expect to give a more detailed account of the process.

The Editor is always glad to receive for examin articles on subjects of timely interest. If the photo the articles sharr, and the facts suthants, the or receive special attention. Accepted articles will regular space rates

The purpose of this journal is to record accurately nply, and interestingly, the world's progress in soi tific knowledge and industrial achievement,

E direct attention to the letter from a mober of the Institute of Chair ber of the Institute of Civil Engineers of Great Britain which is published in the correspondence columns of this issue. The writer takes objection to our recent editorial on "Sea-level Canal and it is evident that he represents the school of English and Continental engineers which believes, or did believe, that whatever might have been its great cost and the added number of years necessary for its completion, a sea-level canal would have been the only satisfactory solution of the problem

the only satisfactory solution of the problem Speaking broadly and as the result of a close per-sonal inspection of conditions during a visit to the canal, we do not hesitate to say that the persistence of foreign engineers in their belief that a sea-level canal is possible at Pansma, is due entirely to lack of inforation, or of appreciation of the actual conditions at the Isthmus. Engineers should besitate to make broad ralizations regarding huge physical underta such as this; for they of all men have reason to know that controlling local conditions may render such gen-eralizations worthless—If our correspondent had stood with the writer at the bottom of the Culebra cut and seen some sixty acres of the mountain sliding into the cut on one side, and seventy acres on the opposite side, at the point of deepest excavation, he would have realized at once that here was a problem requiring separate consideration—one to which broad generalizations should never be applied.

We are still of the opinion that the tidal flow in a neer-level canal would induce an objectionable current; and we cannot understand how the large volume of the Gatun Lake has a hearing upon a question of locks or no locks; since the creation of a high-level lake neces-sarily implies the construction of locks to render it

Regarding the question of earthquakes and their effect upon the canal structures, in the near future we publish an article by the geologist of the Isthmian Canal Commission which most effectually removes any grounds for anxiety as to the permanence of the canal

That the 1,000-foot locks will prove too small for vessels that will seek to pass through the canal, we do not believe We are firmly of the opinion that the demand for greater locks will not come within the "lifetime of the youngest child that can read the Scientific AMERICAN " The 900-foot ships of to-day are built of that great length to meet special passenger require-ments, which are to be found only on the transatiantic But if the day should come wh travel between the two oceans warrants the construction of ships of from one thousand to fifteen hundred feet in length, "M. I C E." if he has any knowledge of topography of the Isthmus, must know that it is not beyond the resources of engineering to construct in the low foothills adjacent to the existing locks, of locks of larger size, and to construct them in t dry, and so protected by dikes at either end of the excavation, that they can be thrown into service without one hour's interference with canal traffic.

The "decree of Nature" that there shall be no sea-level canal at Panama is clearly written in the unstable charactersfor the materials through which the tion of the engineers tell the story of the problem at Culebra in most convicing fashion. On July 1st, 1912, the estimate of the total excess: of excevation for the completed canal was 212,227,000 cubic yards. Eight completed canal was 212,227,000 enthe yards. High-months later, in February, 1913, the settimate had gone up to 214,184,000, an increase of £,521,000 enthe yards; and four months later, on 719 14z, 1913, there was a further increase of over 14,225,000 cuble yards, the total increase during the year being over 20,000,000 cuble yards, and of this about 2,000,000 yards was due to siddes and break in the Culebrar cut. We invite attention to the fact that this increase of 8,000,000 cuble yards was due to a few face lowering of the excavation in the cut to finish it down to grade, 86 feet show the bottom of a sealway again! We have

STATE OF STA

S. G. A. H. G. C.

feet above the bottom of a sea-level canal. W

85 feet above the bottom of a sea-level curst. We save the our correspondent's imagination to forpetell what the increase due to slides alone would be if the cur-wers curried down eighth-wife feet farther. And let it not be forgotten that the angle of repose —the slope—electratined by Nature, is one-to seven. What a further vertical execution of 85 feet would. add to the excavation totals on such a slope nobody can understand better than M. I. C. E. himself. Furthersore, it is very doubtful if admission of water to the move, it is very according a consistent or water to the prisons would help to preserve equilibrium. As a mat-ter of fact, the resulting antenedies of the toe of the slopes would rather trad to present farther movement. We are still of the option that the these of coustruc-tion and the total ultimate cost of a canal at eas level

tion and the total ultimate cost of a onsal at ean level would possibly be double that of the present small. Already, without adding one fact to the preposed depth of the esseration, the total pratings is about one third present than that of the original estimate. True, seem of this is due to an enlarge-small critical reason of the present of the canal dimensions; but the bulk of it is due to silder. A cut 185 feet deeper throughout, would destroy the A cut 85 feet deeper throughout, would destroy the equilibrium in meny miles of the route where at pres-ent no excavation has been made. If we add to the cost of the increase in excavation due to the despec-cut, the interest and despectation charges, and the great-ions in toils due to the delayed opening of the canal, it will be seen that sur estimate of time and cost for construction of the canal at sea level test tests within the bounds of probability

#### Apportioning the Responsibility for the New Haven Wzeck

HE Interstate Commerce Con HE internate Commerce Commission, in its report just issued on the New Haren week, ediase the opportunity to press hems the all-important fact, recently commented upon by this journal, that the safety of the travaling rabble is dependent upon the carriest co-operation of the whole personnel of a railroad, from the Board of Directors down to the humblest employee. It was not necessary for Consistence of the control of the property of the prope train accident." Such treatment was warranted by the fact that the Commission has heretofore expressed in strong terms its condemnation of the management of this railroad, when it has been called upon to investigate the rapidly-succeeding series of fatal accidents that have taken place within the last few years. In proof of its contention that the fundamental cause

dangers of travel on the New Haven Railroad is to be found in the lax system of management, the re port shows that, although the directors, after the West port wreck of 1912 had duplicated the conditions which brought about the Bridgeport wreck of 1911, vote the president "should make the most searching inves gation into the competency of engineers empirithe road," and "that nothing be left undone will conduce to greater safety in the operation of the railroad," the president was never called upon apparently, nor was any other official of the railroad, to present to the directors any results of such investigations as bud been authorised. "The directors," says the Commission, "assume to dispose of their whole re sibility on this subject by a vote depositing it in bulk upon the president, and thereafter as far as appears from the records, made no further inquiry and took no further action, although in quick succession these dis-

The president, general manager and superinten forthwith issued orders that all the rules should obeyed, etc., but no intelligent system was devised by oedyct, etc., but no intelligent system was devined by which to severation when rules were disologied. They were disologied largety, and only a small proportion of these violations were reported to official. "Rules were inhelicient," says the Commission, "a fault of the high difficial. Rules were indecentably entirely, the blams for which must be charged to the official, Asia

iscomotive engineers as well as a Commission of Connections. Take call, arising from the familiar of specially conditions. See a tendence. This call was a public bearings in this case."

Maving placed the predisposing cause disasters upon the shouldest of the s president and the higher officials, the Co our tint the direct cause of the disaster, we of the members of the train serve to obey a exercise the proper degree of caution. The was wholly inadequate—the bands should morely a change of color and not a change and the blocks having no distant signal. and the blocks betwing no discant sugmen-of a proper specing between the trained dispatcher comes in fer hierty eccentra-knew there was a heavy dag, he permitted it rates, running at apeals of from 80 to hour, to be busshed witche a distance miles, with only seven signals properly sehour, to be busined withth a distance has makes with only sevin similar peoplety and the most seving and the most seving similar peoplety and the maximum said speak allowable sider them of fag, yet no specific others or this bees given to the engineers. Commencent sever seem to have run lame of only-busin carrying their principes fright of passesses speed they pleased, regardless of the fact-could not see the signals until they were stram. It is remarkable only that accident character have not occurred to fill like with

#### The Small Eractor

HEN the "impersor" steased up the sea River on one of her resent translate our carried some five thousand people. It is abe is, by far the biggest machine thus far devised for conveying humanity across the cosan, her efficiency is limited. It took a dozen or more small taghosts to push and pull her into her berth so that the thousands on her decks could complete their journey. Every day the "Twentieth Century Limited" hurries business men from New York to Chicago and from Chicago to New York; but a small army of trucks, taxicabs, street cars and carriages is required to transport each passenges to and from the train.

ring a farm is not unlike running the "Imperator" or the "Twentieth Century Limited." While gines are employed in increasing numbers to take the place of draft animals, very large power units are re-quired. The rooting up of trees, the deep plowing of the ground, the threshing of the gasin, the multitude of operations that must be performed on a large firm all consume power in abundance. But there are also, little tasks that must be done, tasks which cannot anne mans that must be done, tasks which cannot be performed by one big machine economically. The orali-nary farm tractor will haul an eight-gang plow or a retime of cultivating implements vary cheapity and esf-cisedty. But when care or potatoes are to be culti-vated, power of a very different aut must be culted into

regulation.

All the mechanical breins of Europe and America have not as yet developed a machine which will deal it kinds of farm work economically and efficiently. The Germans have feeding more fasts than lie within the possibilities of a single American tractor. Their farmes are cultivated on the intended processing the problem of interducing mechanical power is such more difficult with them than it is with us. Yet out of fifty different models of small tractors which have been dereloped in France and Germany, there is but one result commercial machine, and that is pf German manufacture. The commercial success of that solitary mediate depends entirely on its shifty to plow. It quanto real a threshor; it cannot seen having the pends entirely on its shifty to plow. It quanto real and threshor; it cannot seen having the mostly seen handled machines of this type have been sold up to date. sition.

hondred memores date of the date.

Twenty tractors are built in America for each state in Burrops, and each American tracker one doesn kinds or work unknown to the power state Europe. Proposed few Neary Euret at New Yeshes—This Storesary of the Neary recently inspected the site for the new proposed neary yard at 16 New York, suggested by Cape. Van Hissier. Re is preposed to abandon, the present many yard at 16 New Hisse, which it is the Aslawed in worth from traditive to introduce and the Indian distinct Standard over to the day and to locate a new yard, containing bereiting accommodations for forty buttlebility and providing two accommodations for forty battleships and providing two derivations, each 1,200 feet in length, in the shallow part of New York Bay lying between the present channel to the continued of the status of Liberty and New Jersey. Larger accommodation, with thoroughly modern layout; consulting at all low with the continued to the continued consulting at all low with the continued to the great lines of railroad transportation, are the principal advantages to be secured.

principal advantages to be secured.

Crussed Liese Abandeas Queenstown.—The Cuhard Line ansonouses that for the future its steamers "Mauretania" and "Lustania" will make no call at Queenstown, the change being due to the desire to avoid the risk which these large ships inour when they enter that port. A good reason for the change is seen in the fact that on only forty-five occasions out of the one hundred and fifty-four passages across the Allania which these two chips have made, has it been possible to leave the mails at Queenstown. Northering the company will place in service the 900-600t "Aquitania" which will probably be a \$25.8 kmot chip. The change, or far as the public it equiestend, will necessitate a summinant carrier trailing to exist the boats at Liverpool. Queenstown, although admittedity a fine harbor, is too constrained for the safe maniouvering of the giant bulge of to-day.

Sections a push button. Prates No. 1,021,325 describes a push button for an electric doorbell which is provided with a eap that may be turned through an angle of 180 degrees to the right or left to expose the word "out." This will indicate to the caller that no one is at home, and it will be unnecessary for into push the button and waste battery current. If a doctor's offen were equipped with such a button it would prevent the dissurbing of other reambers of the family when the doctor was not in. doctor was not in.

doubte was not in.

Condanziship of Magnesimed Graphica.—Morris

Owes, says the Canadian Repireer, while investigating

the magnetic properties of the elements, found that

graphile was particularly susceptible to magnetization.

This led G. E. Roberts to investigate the electrical

resistance of graphic when magnetized. At first he

experiencested with lead pendla and then with bers of

various graphits. When the graphic wo magnetized

with the lines of force as right angles to the planes of

clearage, the electrical resistance was increased several

insuring per count in some cases.

hundred per cent in some cases. Lighting and Hasting Reposition.—The Imperial Russian Technical Scodety will hold an exposition of lighting, heating, and fire extinguishing devices in Sic Petersburg, from November 1, 1913, to Pebruary 1, 1914. The lighting section will include oil, gas and electric lamps, illustrating their use in the illumination of the home, public buildings, and streets; lighting or advays, engineering, mining works and factorist; in signaling; the lighting of silety differed in theaters; the reproduction of light effects in theaters; the reproduction of moving pictures, photogramsky, essentide work, etc. tography, scientific work, etc.

tograsply, estentific work, etc.

Tanjantames of Good Facetey Lighting in emphasized in a pisper by M. H. Flexuser and A. O. Diober read before the illuminating Brighnesping Society at Pittourgh, Pa. They show that feeding countries have taken up the agreetion a blote more astendarly than we have. They have that feeding countries have taken up the agreetion a blote more astendarly than the have. They have that countries appointed by the government wises circles are to study the efforts of good and bad light on the general basistin, and report upon methods of bettering conditions. Applicately, it is the first cost of the finestination that stands in the way of beyon lighting, and the authors of the paper have endeavored to show holv easily said chemply consistings can be bettered.

how easily and cheapity conditions can be betweed.

New Whiches Bulletins force the Eiler Tweez.—

Since the first of Suptember a special meteorological inuijoint for assimuate inse been sent breachest twins a day,
as 10-68 A. M. and S.P. Mt. by radiotelegraphy from the
Eiler Tower. The morning bulletin instances the brief
report of meteorological conditions at points on both
aboves of the Audania, heretotroe issued for the benefit
of maniners, and, in addition, weather reports from 14
places in western Europa. & Crossat of wind and weather
for France, the force of the wind at the summit of the
Eiler Tower at 7. A. M. and its monhable force during Eiffel Tower at 7 A. M., and its probable force during the afternoon. The afternoon bulletin is somewhat shorter but gives analogous information.

Improvements in Incandescent Lamp Mannfacture.— In a paper by Ward Harrison and Evan J. Edwards, read before the Illuminating Engineering Society, Pitteburgh, Pa., it is brought out that the strength of tungsten Pa., it is brought out that the strength of tungsten filaments has increased more than 300 per cont since 1908, and the strength of drawn wire has increased 40 per cent since 1911. The use of chemicals in the bulb which has become general during the past year has reduced the blacking of lamps to a marked degree and has made possible a substantial reduction in bulb size for everell knaps, thus reducing manufacturing costs and broadening the application of the lamps. The introdu-cion of colled filaments makes possible many new forms of lamps which heretofore oxidid not be manufactured. The strength of the filaments is increased by this process and the quadis-power maintenance is not affected.

The granged of the named is increased by this process and the candis-power maintenance is not affected.

Bleerfesty in Sumatra-Missan.—In Sumatra, the extensive Ombline coul mines are making use of electric methods on a large scale. In the present case the galleries run directly into the side of the mountain and tead to the mines proper which make up three levels. The coult is taken out of the mine by electric locomotives of the entenmary mining pattern which had the trains of small constructives are registered to take the sour down to the levels. As the mines are higher up in the mountain than the railroad station of Savah-Locato, the small locomotives are registered to take the sour down to the leading station upon trolley electric tracks. Parallel to the first electric line has now been man a second trolley mead, but this service for large electric boomotives and one; which, are used for hading station when a second trolley mead, but this service for large electric boomotives and one; which, are used for hading station when a second trolley mead to the first service for his mines. Current is also employed on a large that there is not a place of the service of the mines. The course of the service of the same parallel parallel service is not a place of the service of the same parallel service which we see the service from a steam plant which sends compared him of the parallel service in a high tension space.

Midday Darkness at Glasgow.—British newspapers manday Darkness at Glasgow.—British newspapers report that on June 19th, while violent thunderstorms were being experienced in various parts of Scotland, a dense pall settled over Glasgow, and at noon the city was plunged in midnight darkness. Heavy rain fell soon after.

A Meteorological Station in Greenland was maintained A meceoroopea Station in Greenland was maintained all last winter by Drs. Stolberg and Jost, of the Swiss trans-Greenland expedition, in the vicinity of Godhaven on the west coast (faitude 70). The observer report remarkable alternations of temperature through the winter, coastonal John winds from the east giving temperatures as high as 59 deg. Fahrenheit.

Prince Albert of Monaco, distinguished as an ocean-ographer, arrived in New York Soptember 9th on his yasht "Hirondalle," which is especially fitted up for scientific investigations and carries a large ascientific staff. He left two days later for a shooting expedition in Wyomigs, the yasht meanwhile returning to France. Early in October he will visit the government seismittle visit in the property of the prop

sary in October he will visit the government seienthe institutions in Washington and probably isoture before the Washington Academy of Science.

The Carnegie Engineers Are Safe.—Concerning the fasts of the expedition headed by Dr. Alfred Mayer, director of the Department of Marine Biology of the director of the Department of Marine Biology of the Carnegie Institution, which sailed from San Francisco July 23rd for the East Indies, and was recently rumored to have been meassored by cannihals in New Guines, the disector of the Institution in Washington states that. Dr. Mayer and his party have been heard from since the report of their measurer was circulated and they are undoubtedly safe.

Inflorment with Flants in Great Britain.—The fact that several species of Britain plants, including some of particular beauty and encown, are in danger of extinction owing to ruthless gathering on the part of the public in general and nurserymen in particular, has recently formed the arthur of many communications to the British the subject of many communications to the British scientific journals and newspapers, and was actively discussed at the last meeting of the British Association. obscissed as the last meeting of the British Association.

Opinion seems to be divided as to whether or not the appropriate remedy is to be sought in state protection. Although many wild birds and other members of the animal kingdom are now commonly protected by law in civilized countries, there are few precedents for the state protection of wild plants (one of the few being state protection of wild plants (one of the few being the case of the climbing fern in the United States). The education of public opinion on this subject and other protective measures have been undertaken by a com-mittee of the Schorne Society. One proposed remedy is the establishment of plant and forn sanetuaries, or at least gardens set saids in different localities where every rare British species might be carefully preserved and

The Scott Fund raised by the Mansion House com-mittee in London will be divided between grants to the relatives of those lost in the recent expedition, the publication of the scientific results, and the erection of me-morials. Lady Scott andMrs. Wilson are each to receive £8,500; Captain Scott's mother and sisters, £6,000; Mrs. Bowers and her daughters, £4,500; while £3,500 is provided in trust for little Peter Scott. Smaller sums are allotted to the family of Petty Officer Evans. The sum of £17,500 is provided for working up and publishing the scientific results, which are to be edited by Capt. H. G. Lyons, F. R. S. The memorials will include a tablet in St. Paul's Cathedral, and a group of statuary, which it is proposed to erect in Hyde Park facing the new premises of the Royal Geographical Society. A particularly fit-ting scientific memorial is provided in the shape of a trust fund of some £10,000 for the endowment of future polar research. Although no provision is made for the relatives of the gallant Oates, who need no assistance, the members of his regiment are raising a fund for a

Foreign Names in French Journals.—Carelessness in revesta Names in Frence Journals.—(arcieseness in spelling foreign names is not peculiar to any one country or to any one class of literature, but, with the possible exception of American daily newspapers, there are probably no publications in the world so remise in this respect as the French journals of popular science, while most French periodicals and books of all kinds are not much better. The evil is not merely an offence to the purist, but sometimes has serious practical consequences, as when a reader wishes to consult the original publications of a writer whose work is quoted or abstracted, and whose name is so distorted as to effectually hidehis identity. One of the journals classed above recently referred to Sir Oliver Lodge as "Olaver Ladges," another periodical, apropos of the record halloon ascent of Berson and Süring, transmogrificu the names of these gentlemen into "Berson et Kuhling;" Dr. H. von Floker's recent studies of john winds are attributed in L'Acrophile to one "von Flüker;" and so on, at any in the studies of the seems quite impossible for a Ceruman writer to be satisfied with a single "n" in the final syllable of a personal name ending in "-man." purist, but sometimes has serious practical consequence as when a reader wishes to consult the original public

# How Trees Are Converted Into Paper

A Trip Through a Paper Mill

Fig. 4.—The ordinary type of grinder used in a ground-wood pulp mill.

A GREAT chemist once observed that a nation's wealth could be gaged by its consumption of sulphuric acid. He might have added that a modern nation's culture and refinement may be estimated by its use of paper. Granting this, the progress of the United States must provoke the wonder of the world, for from an unpretentious beginning the American indus-try of paper making has expanded during the past decade until the invested capital amounts to more than \$400,000,000, with a yearly production approaching \$300,000,000 in value.

The raw material of the paper on which the Scien-TIFIC AMERICAN and nearly all books, magazines and newspapers are printed is wood, but the process of desired, and hence originate the different kinds and grades of book, magazine and newsprint papers

Converting Trees Into News Paper. ody of ordinary newsprint paper, such

The body of ordin up the interminable "extras" of a m up the interminable "extras" of a metropolitan even-ing newspaper, consists of a mechanically prepared pulp known as "ground wood," combined with a defin-tic proportion of a chemically prepared pulp, which is called "sulphife" for short, and a certain amount of china clay to impart weight and an even surface to the printed paper.

The term "sulphite" as applied to paper is not so

The term supports as appear to paper is nor so well understood as it might be, even by paper salesman, and it is used very loosely by all classes of consumers, who appear to attach some derogatory meaning to the word. The name is properly applied to the pulp which is produced by boiling a selected wood, usually spruce in a solution of the acid sulphites of lime and m under high pressure, until all its juices, resine and gums, or non-fibrous material, are dissolved out and the skeletons of the plant tissue, countiluting the fibers, In the subsequent processes of washing and bleaching all traces of the suiphite liquor are removed, and the puip so produced represents nearly pure cellulose in fibrous form. Set this is a digression, and in order

return to the basic substance of newsprint paper and

return to the basic substance of newsprint paper and twee the transformation of tree to pulp. While sprace wood was up to a year or so ago alone employed for the manufacture of ground wood pulp, baisam fit, hemick, lodgepole pins, jack pine and mix-tures of these woods are now used largely for the same purpose. This was made possible by a study of gridding conditions undertaken by Government acientory, Wausau, Wis. The wood is first freed from bark, then cut in lengths varying from 24 to 30 inches, or used full cord size of four feet, depending on the form of grinder used. There are only two pulp mills in operation in the United States equipped with the form of magnaine grinder adapted to accommodate a full length log. In the ordi-nary form of grinding apparatus the piece of wood is forced by hydraulic pressure against a revolving grindstone under a stream of water in such a way that the pulpy fibers are torn from it obliquely so as not to divide them, but to pres in their greatest length. rve them as much as possible

in their greatest enter the transfer of pulp flows by gravity to a screening apparatus where the silvers and unground himps are removed, and the liquid pulp then undergoes a number of other screening, straining and delayfirsting processes before it is considered similarinity month and out; for pressing into laps, or is ready for the besting engine, if it is sent the processing that the processing the process if it is not to be stored, but converted directly into paper. In the beater the ground wood receives its admixture of chemical or "sulphite pup?" and the soldsing matter, day, roain and since which go to make up the body of newsprint paper. After the addition of the body of newspritt paper. Fig. 5.—Shredding the baled ground-wood pulp in a Brocklyn paper mill.

Fig. 6 .- Reating engines in a Brooklyn paper mill; each holds a ton of pulp.

end of the machine (illustrated in c am of the macrine (illustrated in colors in a fine artistic conception on the front course page of this week's issue of the SORKETSING AMBRICAN) inskes demands on the machine bunders which necessitate tant watchfulness and no little degree of muscular strength and activity of movement. If the stock has not been carefully ground and beaten, breaks are likely to occur with exasperating fre-quency and necessitate stopping the dryquency and necessitate stopping the ary-ing cylinders until the sheet has been caught and freed from a possible entan-glement in the upper or lower tiers of driers; measurable the pulp at the wet end of the machine may be draining as "white water" to be pumped bac later through pipes and acreens to the flow box, from which it again resumes its course over the traveling wire in the

direction of the press rolls.

The idea of a machine for making contimous rolls of paper was conceived by a Frenchman, Nicolas Louis Robert, in 1708. The machine constructed by him did not The macains constructed by him did not produce a web of indefinite length, but one limited to fifty feet. An endless band of wire screen ran over two rollers. The pulp in the vat was conveyed to this wire by a blade wheel over a breasting. In its passage over the wire the water drained from it passed back into the pulp vat, which occupied nearly the whole of the lower portion of the machine and was ed over and over again, as at present. The machine was worked by hand.

The Fourdrinier brothers (Henry and Sealy), whose name is perpetuated in the rn paper-making machine, obtained patent rights on the machine invented by Robert, in 1806. The paper made on the machine used by the Fourdriniers in their mili at Frogmore, England, was twelve es to twelve feet wide, of a length not exceeding fifty-five feet. The machine was not equipped with a drying cylinder and the paper had to be taken off wet and hung up to dry.

It is a far cry from the days of Robe and Fourdrinier to the present time, when the Fourdrinier parts of a paper machine are made in instances of a width of 202 inches, while the wire, 200 inches wide, is capable of be ing aper ed up to 808 feet a minute to make a roll of paper eight miles

What is "Sulphite" Pulp? perishable nature of ordinary n print paper is due to the presence in the ground woodpuip of the sup, lignin and resin of the tree, substances that oxiding the paper and make it brittle. The sul-phits process rields a pulp that is free from these objectionable products, which from these objectionship products, which are decomposed in the socking of the wood, or dissolved away and more or less completely washed out with the first wa-ages active the pulp is discharged from

parters, plate pulp in manufactured shiely springs wood. The wood having besting due to have been a present of the hart, others, the present wood process, is

Fig. 8.—At the couch roll where the wire reverses. Here the delicate gauzelike tissue is lifted from wire to roll.

Fig. 8.—At this point the paper begins to form on the Fourdrinier machine. The machine attendant is fusning over the "doctor," which scrapes the roll.

chimsel up into small pieces or chips about one fourth luch to a haif luch thick and boiled under pressure in large steel digesters capable of holding twenty tons of wood at one operation and yielding ten tons of finished pulp. The digesters are lined with heavy cement backing, faced with brick, pointed with lithurge and glycerin to avoid contact with the metal, and the huge steel cylinders are fortified against bursting under pressure and extremes of temperature by butlstraps on the inside and outside of the shell of steel.

The sulphite liquor in which the wood holled is made by passing sulphur dioxide—obtained by burning either supplur or iron pyrites in special ovens luto tanks filled with water and a known quantity of slaked line (prepared from dolomite) This results in the formation of a solution of the acid sulphites of cul cium and magneshum, which is the active solvent agent Ordinary limestone is used in many pulp mills, but dolomite ylelds a more powerful extractive solu-

When the digesters have been filled with the wood chips and the requisite quantity of sulphite liquor is udded, the manhole or cover at the top of the dige is securely fastened and steam turned on gradually nutil the pressure reaches seventy or eighty pounds. The cooking is stendly maintained at this pressure for a period of eight to ten hours. At the end of this time the contents of the boller, consisting of the disintegrated fibers of wood, are discharged into large vats and washed. The spent liquor containing the dissolved resinous and non-librous portion of the original wood is allowed to drain away, and the tank is then washed out and made ready for another

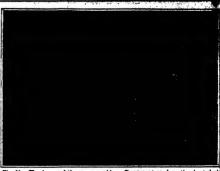

Sulphite pulp is increasing in use throughout the country. The quantity used during the decade 1899 to 1909 increased 781,759 tons, and of the cuttre quantity of woodquip used in 1999, the quantity of woodquip used in 1999, the latest census figures available, sulphite pulp constituted 42 per cent as compared with 356 per cent in 1899 The output of sulphite pulp hereused 1446 per cent dur-ing the decade and that of ground wood pulp 101 1 per cent. A constant's increas ing amount of sulphite pulp is imported annually from Camada, Sweden, Norway

#### The Process of Making Soda and Sulphite Pulp. The soda process, yielding so-called soda

putp, is used for soft woods like poplar, cotton and basswood, whereas the sulphite process is exclusively employed for contferons woods. The chipped wood is boited in a solution of caustic soda for eight or nine hours at a pressure of seventy or eighty pounds. The pulp produced is soft and bleaches well, making it espe-cially well adapted for the manufacture of book and magazine papers. The better grades of magazine paper are composed of a mixture of suinfitte and sods online and these, if thoroughly well cooked and

-The paper is now fully formed and on its way to the drying rolls, of which there may be as many as forty in a large machine.

-The dryers of the paper machine. To prevent condensation heaforced into the room and a current maintained by exhaust fans. is forced into the rec

carefully bleached, are almost equally as permanent as rng stock

Sulphate pulp is prepared by bolling the wood chips in a solution of sodium sulphate containing some causthe sodu and sodium carbonate. It is a slower process than either the sulphite or the soda, as the period of bolilug Instead of being eight or nine hours is some times extended much longer, though good results have been distilled with a modified process in which the period of cooking is much shortened. The process is more economical one than the simule caustic sode since, notwithstanding the case with most of the netive chemical agent is recovered in the latter, there is still a loss of 8 to 10 per cent, even with efficient recovery plants. In the sulphate process this loss is made up by the addition of sodium sulphate (Glauber's vit) in the place of caustic soda, thus effecting a c asiderable economy, as the price of cus-tic is much higher than sulplute. The principle of the process depends on the fact that in soda recovery, when the concentrated liquors remaining after all the cellulose has been extracted from the wood are burned to ash, the sulphate reacts with the organic matter in the liquor and is thereby reduced to sulphide, and by sence in the liquor subsequently made oxidation its presence in the induor sunsequenty made optication of the fiber is prevented, so that a good yield of strong pulp is obtained. The so-called "kraft" papers are made by this process, which is not a popular one, as the gases formed have a very offensive odor, like that of rotten eggs, which affects the whole neighborhood of the mill and makes the atmosphere almost unendurable. The manufacture of sulphate pulp promises the de-

velopment of a great industry in the Southern States, where there is an abundance of raw material in the pines indigenous to that region. The profitable dis-position of the whole timber as well as the waste and stumpage of southern place in the manufacture of paper pulp is a problem on which the Forest Products Service

of the United States Department of Agriculture has been working for the past two years, with very encouraging results. It has now been established that long leaf pine is well adapted for the manufacture of nat ural-color "kraft" pulps and paper, the heavy brown wrapping paper of the stores, and that by the sulphate process a grade of "kraft" paper can be made equal or superior in quality to the imported or domestic "kraft" papers now procurable. A large company has been recently organized to build a mill in Florida, and this ls regarded as the entering wedge for a number of

# The Disposition of Waste Liquors One of the weightest problems confronting

One of the weightest problems confronting the manufacturer of chemical pulps to-day is the disposition of waste liquors. He is eager to be informed of a me of utilizing the spent lyes from the sulphite process that would obviate the present necessity of throwing them into rivers and streams in such large quantities

as has been done up to the present time.

By neutralizing the waste sulphite liquor and starting fermentation of the contained sugars, alcohol of ing rementation of the contained sugars, alconol or a low grade is produced from it in several pulp plants in Sweden, and by a patented concentration process used in the 'inited States, a compound is separated, which is utilized as a binder in road making, as a tanning extract and as an adhesive for sand in making molds and cores for iron in foundries. But the profitable recovery of the organic matter dissolved from wood in the sulphite process is still an unsolved prob lem, notwithstanding the fact that it has been deeply studied by able chemists for more than twenty years

In the sods and the sulphate proces making there is effected a partial recovery of materials and of power, by incincrating the spent soda liquor, after evaporating and concentrating it, the soda lixelf is regenerated, but there is a total loss of the organic

derivatives of the wood, which are burned up in recov ering the soda

oring the soon.

A Modera Tendency in Manufacturing Paper.

Ten years ago it would have been deemed exceedingly difficult, if not impossible, to operate a paper mill at any distance from the sources of supply of wood and of power, that is to say, from a well watered forest region, but during recent years, in the progress retire region, but during recent years, in the progress of the paper-making industry, water and steam have been generally displaced by electricity as motive power, developed by turbo-generators, and the machinery of modern paper mills is driven by direct-connected motors in place of the shafting and belting which dised the older mills.

An interesting development in the manufacture of An interesting development in the manufacture of newsprint paper is being witnessed in the harbor of New York, a paper mill having been constructed on the South Brooklyu waterfront with a capacity of 100 tous a day. The ground wood pulp is manufactured in Canada, and brought to New York Harbor in car-ces of 5,000 tous by steamship and landed at the dock from the manufacturing plant. The pulp arrives in bales weighing about 400 pounds each. In a building on the dock the pulp is passed through a shredder, where it is fluely divided and agitated with water until it is reduced to a fluid form, when it is pumped directly to the beating engines in the mill proper. As the pulp enters the beaters, of which there are six (three for each paper machine), each capable of holding 2,200 pounds of material, there are added to it 20 per cent of sulphile pulp, the clay, coloring matter and sking which complete the "furnish." The mass is beaten and circulated in the engines for one hour, after which it passes down to a large concrete lank in the basement, called the "stuff chest". Here it is diluted with a large quantity of water. Next it is drawn up by powerful pumps and passed through a Jordan engine

Fig. 12.-The "dry end" of the two large mach ines which are shown in Fig. 7. The machine in the center make s paper 194 inches wide at a rate of 880 feet

#### Sea-level Canal Fallacies

To the Editor of the Scrawfirst American: I have been considerably interested in reading your criticle on the above subject in your sens of the 16th

doubt that this article will invite o

a mew no course max this arrace will livite con-troyers, as I do not think that your correspondent's views are altogether sound. There are many critics, I imagine, and also some of the best engineers in the States, who pelieve that it might have been possible, and indeed better, to have built the Panama Canal at

Sections.

You say that you doubt that any engineer could be found to-day who would advoasts such a canal. I do not think that there would have been any difficulty in finding such an engineer, but would prefer not to mention

names at the present time.

Further, I do not understand why you lay down as a kind of axiom that any kind of a canal at Panama must kind of axiom that any kind of a canal at Panana must be provided with looks. When we consider the com-paratively short time of tidal flow, that the canal is nearly 50 miles long, and that the Gatun Lake has such a large volume, does your correspondent seriously put toward that this ten feet difference of tide would cause such a current as to render navigation difficult, especially

in a canal with such a large cross section?

Judging from the experience in the Manchester Ship Canal in England and in other ship canals in Canada and the United States, I do not believe that the our

and the United States, I do not believe that the ourrent would be large or difficult to navigate. With respect to the question you have raised about the size of ships, as the locks will certainly out-live (the effect of carthquakes excepted) the "Ille-time of the youngest onlid that can read the Scheritz Cantincan," I do not think that your argument is a reasonable one, and do not see any reason why in some future, ships using the canal abould, not be existing which would

sups using the caloat about not be existing when would require long-looks than those provided.

Later, you say "nature has decreed that no sea-leve canal shall ever be constructed at this isthmus." I do not think that there is any evidence of such a decree and I do not believe that there is any doubt that a sea-I do could be constructed

The Culchra cut is certainly a deep excavation, but nould the further 85 feet below the present bottom of the prism prove to be rook, there would be no further fifculty caused by the slipping of the slopes; should, waven, it was the slipping of the slopes; should, should the further 85 feet bele owever, it prove to be soft, certainly, as a last resource this extra depth of the cutting could have been removed by dredging, in which case the water would assist to support the sides of the prism.

In your last paragraph you practically say that it may be stated that if the canal were cut through the "divide" down to see-level, the time and cost of con-struction would be doubled 1 do not see any reason to believe that such a "hard-and-fast" statement would

Finally. I have heard it stated that the canal is being d as a lock canal on a minority report, and that this was done for the reason of expediency; if this be so It would certainly show that some well-known engineers believed that the sea-level canal was not only possible, but certainly desirable.

I am now crossing over to Europe, and hope that you will have some further reference to this interesting subject

from your correspondents.

#### Prevention of Aviation Accidents

MANN TERCAMBULATION AND A STATE OF THE STATE

To the Editor of the Scientific American:
The recent fatal accident to Emign Billingsley of
the U. S. Navy, with the miracle-like escape of his
companion, Lieut. Towers, would seem to furnish an explanation of many other aviation accidents and suggests two things that should be done to prevent similar accidents in future. The survivor explains just how the mishap occurred, an upward wind gust having oridently struck the tail, or rear elevator, causing the machine to suddenly dive forward and downward, throwing out Billingdey, who was huried 1,500 feet to his death, while Towers dung to an upright and survived when the machine crashed into Chespeake Bay. A quite similar acoldean briefl an acrosspeake Bay. A quite similar acoldean briefl an acrosspeake conceeded in regulaing his seat and righting the secreplane sites being thrown forward from his seak when a warm, seanching sit current evidently struck the rear: elevator. Harrist Quinby and the passenger wave thrown out one one control to the control of how the mishap occurred, an upward wind gust having tion the numerous other aviators who are I have periahed similarly. The two lessess to b

from these cases are: First, that the aviator and sengers should be held in their seats by a strap or sin sengers meren, so ned in their sease by a steep or similar device pissing in front of them but of course instantly removable when desired, and second, that all acro-planes should be provided with both front and rear elevators, so that in case of a strong ascending or de-seanding current striking one but not the other, or satiking them at different moments, the opposite one would instantly oppose to a great degree any sudden upward or downward movement, even before the water could adjust the elevators to counteract the movement; for with the two elevators connected be rear flap were forced upward despite the aviator's grasp on the lever, the front flap would turn downward to elevate, as needed, anticipating or at least aiding his movement of them; and if the elevators included little or no fixed horizontal surface, but simply consisted of planes pivoted at points much nearer front than rear of them and turnable through sixty to ninety degrees, with stops on each side, such upward or downward air currents could not materially upset the longitudinal balance of the machine; but if, with consideral fixed horizontal surface attached, the strong upward or downward current, acting on it as on a sail, should break or disable one elevator, the aviator would still break or disable one elevator, the aviator would still have the other one to depend upon for said landing, more especially if each elevator were connected by its cable to a separate lever, with the two levera arranged side by aide so as to be grasped in the one hand, and by having pulley bell-lightoners attached to such or one elevator cable the relative angles of the two ele-vators could be changed during flight or set as found best by means of levers connected therewith.

In conclusion, the writer is convinced that all aeroplane controls should be duplicated. For instance, the ordinary rear vertical rudder for lateral steering, and ordinary rear vertical rudder for lateral steering, and on which the lateral balance so much depends, especially at times, abouth be duplicated at the front (as I believe is done only in Capt. Cody's machine), or else pivoted vertical resistance surfaces could be easily provided at the lateral ends for steering purposes, as in some seroplanes, or all three steering methods used, two or three levers being preferably arranged to be grasped in one hand for the purpose, as above described; for a contraver side cust may be a suppressed as the contract of the purpose of the purpose of the contract of the purpose of the contract of the purpose. graped in one hand for the purpose, as above described; for a contrary side gust may sometimes prevent a rear or front vertical rudder from steering the erast as desired, or as necessary to preservo balance.

By using such duplicate controls, the writer believes

By using such duplicate controls, the writer believes that aeroplaning will be made as and as at lever can be; for I venture to predict that the successful, safe, and efficient flying machine of the near future will be a combined helicopter and aeroplane. It is with the hope that these suggestions may help to lossen the death toll of aviati on that they are here given, and ore may follow later. ELMER G. STILL.

#### Fire Protection by Automatic Sprinklers

To the Editor of the Scientific American: The second editorial in your recent number referring to the disastrous fire in Binghamton is all right so far as it goes, but it strikes the writer that it missed one of the strongest points which could have been made with regard to improvement in conditions which would

make impossible a repetition of such catastrophe.

In the August number of the Journal of the American clety of Mechanical Engineers, the case is vory well nd 1273, as well as, in a certain put on pages 1272 as sense, the remarks at the bottom of page 1269 and top of 1270. Particularly in the middle of page 1272 is the point made clear, that every time a sprinkler operfrom fire in a building full of people, it is a potential

The writer has been studying this subject of Automatic Sprinklers, and their use in saving both property and life, for some little time. So far as I have been able to learn, there have been just eight deaths b fire in factories protected by automatic sprinklers. It not a single one of the eight cases could the death be charged to the failure of the sprinklers to operate prop-

onaryon to the faint of the spiniaries to operate pro-erly, as you will see by considering the details. In January, 1907, under peculiar circumstances, a fire gained great headway in the Cocheco Mills, Dover, New Hampshire, at a time when the automatic sprinkler system had been temporarily shut off for adjustment This was a cotton mill, and the spread of the fire was so rapid in the cotton goods on the machines, and up through belt ways, etc., that five of the employees, who attempted to save their belongings in their lookers, were overcome by smoke, and lost their lives. The were overcome by amoke, and met their rives. The agrinkiers were not operative at the time the fire broke out. Before they could be adjusted and put in service the damage had been done. This is, of course, a strong argument in favor of kepting all such equipment at all times rused for immediate service.

times ready for immediate service.

About a year ago a celluloid comb factory near Boston was the scene of a fire which flashed all around the room in the scraps of extremely infianmable celluloid on the work benches, making a complete circle of flame, which suit off the access to the stairs. About dosen employees in the room deshed through the

flame and down the stairs, all being more or less severely burned, and two of them losing their lives. Please note: Before the fire department arrived on the scene the automatic sprinklers had the fire completely out. would, of course, be too much to have expected I t. employees to remain within the circle of fiame for sixty or ninety seconds required by the sprinklers to put out the fire. Probably no human being under h circumstances, and with the panic which is always nected with fire, would have remained at this time. It is perfectly clear that if all the employees he in the room, the chances are that none of them would have been severely injured.

The other case where life was lost under automatic sprinklers was in a plane factory in New Jersey also about a year ago. The watchman's lantern expleded, while he was making his rounds, and set fire to the inflammable varnishes in the room through which he was passing. He was so severely burned as a result of the initial explosion that he died the next day. The sprinklers held the fire from spreading, giving the fire-

men an easy task in putting the fire out.

Practically every expert who reported upon the results of the Asch Building fire in New York two years ago said that automatic sprinklers would probably have prevented the loss of life in that building. As you probably noted, automatic sprinklers have been since installed throughout that building.

The National Fire Protection Association shows ords of some 15,000 fires in which automatic sprinklers have figured. The three cases above mentioned are the only ones in which loss of life has occurred, and the es, in those cases, were so peculiar that as matters stood, the sprinkler may be said to have a clear record, so far as life saving is concerned The matallation of fireproof stairways will do much

to help matters along They are, however, no means of surety against panie, and should be considered simply as one of a number of devices, all with the same end in view. They would probably be more expensive to Install in an existing fire-trap than would a satisfactory system of automatic sprinklers. They would be less effective as a life-saving device, and not at all effective, from the dollars and cents standpoint upon the saving of property. Sprinklers would save both lives and property, and pay for themselves in a period of four or five years, through reduction in insurance rates. Which, under these circumstances, do you conder the better scheme to advocate?
So far as the fireproof building is concerned, the

starway will not make it more fireproof, and in very tall buildings, such as some of the loft buildings in New York, the space requirements for such a stairway to accommodate hundreds of operatives all at the same time, would be prohibitive. The sprinklers, by confining the fire to a more handful of flames, so to speak, would make it unnecessary to empty the building in any such hurry, and would soon come to be recognized in its true light, as a life saver and a panie det

Cases are on record where a fire in a waste basket full of paper has been put out by a sprinkler before the waste basket was consumed. The sprinklers operate without human assistance, are not subject to conditions or excitement, are not hampered by smoke or a sudden flash of flame, are not hindered in their work by a rush of frightened human beings running away from the seat of disturbance

To my mind they are the only great saving factor in our fight against fire, and should be required (legally) in all manufacturing plants subject to destruction.

They can be put into existing buildings at nominal onse, and render what is now a fire-trap, more as against both panic and lose of life, than any fireproof" building now existing, which does not contain sprinklers. If you consult the real estate adver-tising pages of the New York Herald you will find building after building designed for loft and manufacturing purposes making capital of the fact that they are pro-

teeted by automatic sprinklers.

I have nothing to do with sprinklers from any business point of view. I am, however, intensely interested in the very live subject of the conservation of life and SIDNEY G. KOON. ımulat d resource

Boston, Mass

[The writer of the above letter is in error in his supsition that the editorial referred to advocated the building of fireproof stairways as the sole protection against fire; nor will even a cursory reading give this impression. Automatic sprinklers are one very efficient and well-established method of fire protection, as the facts given in the above letter will show.—Editor.]

Street Accidents in London have increased at an alarming rate with the increasing use of automobiles. Giving ing rate with the increasing use of automomies. Giving evidence before a parliamentary committee on motor traffic in London, Colonel Hellard, chief of the London traffic branch of the Board of Trade, recently stated that in the metropolitan area last year there were 537 deaths from street accidents, as compared with 155 in 1904, while over 20,000 persons were injured, as comared with about half that number in 1904.

New machines that produce cold.

# Recent Improvements in the Refrigerating Industry

#### What the Inventor Has Done for Cold Storage

While cold can be produced striftening ways in the compression, the absorption, and the sir expansion events are of commercial importance and they remain the compression. The theory of operation of all three is comparatively simple, atthough in order it obtain the highest efficiency onch apparatuse is at times somewhat complicated. In all three types a substance known as a heat cerrier, taking up heat at a low temperature in the cooler and discharging it infor unmine water. In order that the refrigerant may perform this function, work must be done. The refrigerant most generally used in the compression system is analytican earlier under all the compression system is analytican ends, although cerbon dioxide and subject doxide are

It will be seen from Fig. 1, a diagrammatic view, that the compression system causals of four main parts, a compressor, a condenser, an expansion valve, and an evaporation or refrizerator coil. The compressor, in effect, is a best pump, as it enables the retrigerant to perform its function as the heat carrier. In operation, it pumps ammonia wapor out or the retrigerator coil and forces it under high pressure into the condenser, where it liquefies, due to the high pressure maintained therein, unasily about 175 pounds for emmonia, and to tecoding effect of the water fowling over the pipe coil. The heat removed from the amounta in the condenser is of two kinds; that its, sensible heat or heat put in during compression (all games generate heat when compressed) and the latent theat which the ammonia gives up in peaking from the gameons the liquid state. The liquid ammonia then passes through the expansion valve into the refrigerator coil where it again evaporates or boths by reason of the heat from the substance to be cooled. As fait as the vapor is given off it is pumped out by the compressor, and it is essential that the pressures be kept comparatively use, for the holding temperature of all liquids depends upon the pressure. Under 15 pounds pressure ammonia belies at zero Fahr.

It will be noted that the cooling effected is due to the general heat absorbed in passing from the liquid to the general state, and not to the expansion of the ammonia gas. The latest heat of ammonia is very marked one opened of liquid ammonia e-vapivating at 15 pound-pressure, is sufficient to convert over four pounds of some pressure of the pounds of the pressure of

It is absolutely essential that the animula be in the liquid form as it enters the cooling cell, for otherwise no cooling will be effected. The compression system was invested by William Cullen, an American, who took out an English patent in 1755. This system did not come into general use, however, until about 1870, when ammonfa was introduced as the refrigerant.

ammonia was introduced as the refrigerant.

The absorption system was invented by Ferdinand Carre, of Paris, about 1890. In this system the compressor is replaced by a vessel partially filled with water. When cold the water readily absorbe all the vapor from the liquid ammonia evaporating in the refrigerator coll and forms the ordinary strong aqua ammonia. This aqua is then heated and the ammonia gas in dry or anhistrons condition is driven off under high pressure into the condenser, where it is cooled and liquefied in the same manner us in the compression system. In this simple form the machine is intermittent in its cooling, but by undar a separate absorber and a pump to cause the liquid to circulate through the boller and the absorber, the cooling operation can be made continuous. Absorption machines are still extended in the condense of the control of the control of the continuous.

Not more than the companion medithe was more generally used than elliner of the two others mentioned alove. It was havented by Dr. Gorrie of Apinchicola, Florida, in 1845, and was used for ranking to. The machines have the same elements as the compression matchine, except that the expansion valve is replaced by an expansion engine. As the air is not liqueled in the condenser it would not effect any appreciable couling if allowed to expand freety through an expansion valve, but if allowed to expand ganjust a movable placeman of the condenser it would not effect any appreciable could not so the condenser it would not effect any appreciable could not so the companion of the condense is not contained to the companion of the compani

While the artificial refrigeration industry is one of comparatively recent development, its growth has been very rapid, and it now plays a very important part in the conservation and distribution of our food supply. The improvements in retrigerating apparatus and methods in the last decade have been numerous and important. These changes generally relate to improve ments made in the construction and operation of the

various integral parts rather than to the machines and processes as a whole, and to the extension of the industry to new fields.

Often in cold storage systems II is desirable to main-

Often in cold storings systems II is destrable to mathem different temperatures in various compariments; also in ice making the temperature of the fore cooler should be higher than that multishined in the freezing tank. As the temperature in a refrigerating odd is dependent upon the lack or suction pressure, it is obvious that it would be difficult to maintain such difference in temperature by an ordinary compressor. To overcome such difficults, the compressor shown in Fig. 1 was devised. During the first part of the auction stroke of

this compressor, low pressure gas is drawn in from the freeding col, and when the piston is near the end of its stroke, a part is uncovered, permitting gas of a higher pressure to rish in from the fore cooler. In this way the eythind becomes filled with gas of the higher pressure maintained in the fore cooler and on the retring stroke the part is quickly covered; the gas is conpressed and driven into the condenser. As the refrigering capacity of a compressor is proportional to the absolute back pressure at which it operates, it is obvious that this multiple effect arrangement greatly increases the capacity of the compressor, and especially as where carbon dlackle is used as the refrigerent

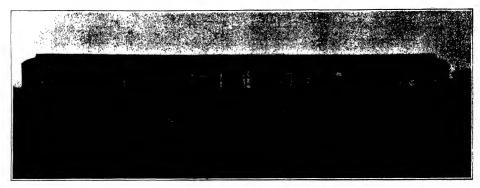

sat where carron maxime is used as the refrigering.
The quadruple acting compressor shown in Fig. 2, is
a more recent product. About milway of the bare of
the cylinder by placed a partition which also knows
discharge valves. The two plotons have bollow platon
rods provided with check valves for the admission nor
despined to keep down the heave for the admission of
gas to two of the compression squees. This feature is
designed to keep down the heart generated during compression. It is obvious that this compresso has a
large expactly for its slow.

It is probable that less effort has been made to harprove the condenser than any other me part of the
friberating machine. For many years condensers were
generally so constructed that the hol gas entered at the
top of the coll and the liquid condensed was drawn off
at the bottom. Heccurity, however, an improved form
shown in Fig. 3 was hirtofuced, in which the hol gas
was made to enter at the bottom of the coll instead of
the top. This simple change made it possible to reduce
the size of the condenser one half or more and still
obtain more satisfactory results than with the old form.
This is due to the fact that the transfer of heat from
the hot refrigerant holds the coll to the condensing
water is about four then as rapid when the refrieerant

(Continued on page 272)

# A Car Designed for the New Subway

Providing 42 Per Cent More Seats and 100 Per Cent More Standing Room Per Passenger

Full-size model in wood of new steel subway car for New York Municipal Railway Company

I N rapid transit service, the number of passengers that can be carried in a given time over a given length of road is determined, not so much by the speed of the trains between stations as it is by the time occupied at the stations in discharging and taking on pas sengers. In most large cities, the rapid transit bassenger asks first that he be taken to his destination as quickly as possible, second: that he be given a seat.

On the present subway of this city, as operated by the Interborough Company, the express platforms are about five hundred feet in length This dimension determines the number of cars that can be run in a single train, and the express trains as now made un consist of ten cars which, if louded to their maximum stilling and standing capacity, during the rush hours can each necommodate twelve hun-dred people—this, be it remembered, representing the maximum possible accom-modation when there is heavy congestion of trof-fic. Of the hundred and twenty passengers crowded into each cur, forts four six standing

The New York Muni cipal Railway, which will operate a part of the new dual system that is under

construction, has designed a new car, in which they have sought to provide, on the basis of 1,200 people per train, a larger seating capacity, and a less crowded standing space for those who cannot secure seats. Also, by making a better distribution of the three cutrances to each car, they have facilitated the toading and unloading of passengers, and so have cut down the time

The new car will, of course, be built entirely of steel; but to demonstrate to the Public Service (

and to those who are interested in the proble erni external and interior appearance of the car, the comfort and convenience of the seating arrangements. and the freedom of ingress and egress, the company have built at their yards in Brooklyn a full-size i car, of which we present the accompanying illustration

It will be noticed at once that the car is very much larger than those in use in the present subway. The end platforms—which should have been abolished from

Interior of car, showing seating and wide standing snaces.

subway and elevated service long ago as an obsolete survival of the early days of raitroading—is omitted, and the whote 67-foot length of the car is available for seating accommodations. The width of the car is 10 fect. As compared with the present subway cars, the new model is 15 feet 7 inches longer and 15½ inches wider. Each train will be made up of eight cars as st ten in the Interborough trains, and the total length of the eight-car train will be 538 feet 4 inches, agalust 513 feet 5 inches. The total space in

feet as against 3.702 square feet in the ten-car train.

In the Interborough cars there are a center door, and two end doors on the platforms; on the new car there is a center door, and a door at each side of it so spaced as to give the minimum amount of move for a passenger in passing from his seat to the door or vice versa. The guard stands in the center of the car on the side opposite the station platform. He stands on a platform suffi-

clently elevated to enable him to see clearly each set of doors, which he opens and shuts by pressing electric buttons that operate nn electro-pneumatic sys-tem. To prevent the motorman (every car is a motrain until every door is shut, the door-closing mechanism is so connected, electrically, with the controlling lever under the motorman's hand, that he cannot start the train until the last door in the train is closed, and an electric light signal in the cab has given him notification.

We draw attention to the accompanying table com-paring the proposed car with the present subway car. The most significant relative seating and stand-

ing capacity, from which it will be seen that the stand-ing and seating conditions are vastly improved.

COMPARISON OF SEATING AND STANDING CAPACITY ON A BASIS OF 1,200 PEOPLE PER TRAIN.

# A New Mail Carrying Railway

A Parcels Post Tunnel

View of the inner circle, showing the tube at the far side and end, with a two hundred and twenty foot trestle on the right. The trestle represents a twenty per cent grade.

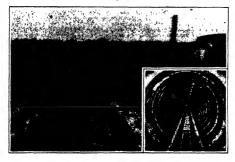

THE advent of the parcels post has created a demand for some means whereby large numbers of parcels may be transported by a more expedition less easily interrupted system than the less cashly interrupted system than the horse-drawn vehicles or motor cars at present rolled upon. The Government's interest in the matter was shown by the appointment of a commission recently to investigate the feasibility and practicability of an underground tunnel between the new post office, located at the Pennsylvania Raifroad station, and the Grand Central terminal in New York city, a tunnel large enough to transport mail in sacks. In five of our big cities, namely, York, Chicago, Philadelphia, Boston, and St. Louis, a large part of the first-class mull is transported between the post office and branch stations and railway stations through underground pneumati-These tubes are eight inches in diameter, and the letters, tied up in small bundles, are dispatched in steel carriers which fit like a piston in the tube, and follow one another in rapid succes while these tubes are adequate enough for ordinary mail, they cannot handle the larger backages which are sent by parcels or large sucks of letters. Ol a mail-carrying system is demanded which will fulfill these requirements. Hardly had the parcels post been definitely established when several companies immediately entered the field with proposals to build tunnels which would handle the bulky mail matter of the parcels post.

One of these systems was described in SCIENTIFIC AMERICAN of January 4th, 1913. Another has been experimentally tried out at Paterson, New Jersey.

The Paterson system represents about seven years of continuous effort to produce an electric carrier system of commercial form. As it now stands it seems adapted not only to propel parcel conveyers, but also elevators, excitators, moring alsewalks and even the rolling stock of standard gage refireds. A 14-fact model was installed some time ago at the Bush Terminal. It attracted much flowrable comment at the time. It was not, however, a full-sized commercial plant, complete with terminal buildings, switches, strategy and strapping devices, and the law, which the strapping devices, and the law, which

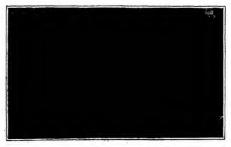

And the second

Bally Windows .

The structure viewed from the top of the treatle showing the terminal building in the distance.

The sumii insert is an inside view of the open structure, showing the fixed motor member between rails, the other motor member being attached beneath the car. There are two conducting rails, for two phases of the current, the third phase being grounder.

The car used in experiments

The workmen were photographed inside the car to show the relative sizes of the parts. All the car space is available for freight. The cars weigh 1,200 pounds and take the grade easily with a then per cust slip from synchroneus speed under a load of 1,500 pounds. would afford a real demonstration under actual conditions to business men and government officials. Such a plant, however, is now to be seen at Paterson, New Jersey.

At the Paterson plant 36-inch tubes have been built in these tubes cars run on rule and are driven by alternating current supplied by combacting rule. The cars are provelled by magnetic push or pul, without wheel traction. In other words, they are swent along by the progressive magnetic field produced by the reaction between a flut motor member, at tached to the bottom of the car, and an elongated motor member affixed to the track between the rule. Both members of the motor are made of infinished from The fronts of the car member contain once dreat wire windows, those of the track member, closed circuit windings of the squirre (age (1))e

Since there is no rotary motor, no gentings, no armature, no commutator, the cars require neither offing nor attendance Hence the cost of operation and maintennace is reduced to a comparatively very small figure

Regardless of their number, the enra nar instantly obsellent to central control. They can be started, specified up or slowed down, stopped or reversed by pressing the buttons within courter the current supplied through the two feeder ralls, without shock to the cars, contents or track. At any predetermined point, the ears may be switched automatically from the until line to branch lines, or from branch lines to the math line, without affecting the movement of ears which are tunning before or behind the shunted cars.

The longer the line, the more rapid, reliatio, economiest and efficient will be the operation. Write it has been estimated that a system constructed on the dimensions of the Paterson plant, possesses, currying enactly sufficient to transport will the mains and express matter meeting between any parts of London, Parts or New York, it may be designed on any diameter necessary to handle small east the stock of the paterson of the paterson of maintain and the towards of the paterson of the

## The Heavens in October

#### The Newly Discovered Comets and Their Orbits

By Henry Norris Russell, Ph.D.

A FTER a considerable interval, during which no comets appeared, two have been found within a few days of one another.

The first was discovered by the liev, J. II Meteuk, as Nouth Here, Vermout, on the night of September 1st—cridently while this well known and successful astronomer was endoving his vacation. It appeared to be of the ninth magnitude, and showed a slow north-the ore; motion. The discovery was, as small, telegraphed to the Harvard, whence the news was spread to astronomers generally.

A photograph taken at the Yerkew Observatory by Prof. Harnard, on September 5th, with four lours' oxposaire, showed the comet as a runad, condensed nebulostly without sux tall. A providenial cribit of this comet, based on observa-

A provisional orbit of this comet, based on observations on September 2nd, 3rd and 4th, shows that it was just approaching perthelion when discovered, and reached that joint in this orbit on September 14th, at a distance of 122 million mile from the Sun. The plane of its orbit is inclined about 37 degrees to that of the celliptic, and its motion around the Sun is retrograde, that is, in the opposite direction to that of the Earth

The second conet was discovered by the Russian acronomes. Neulini, four days after the first I's orbit ins also been calculated, and it appears that it, too, was just approaching perhelion when discovered, and will be nearest the Nin on October 3rd. The parabolic orbit first calculated gave the rather large perhelion orbit first calculated gave the rather large perhelion orbit first calculated gave the rather large perhelion orbit first calculated gave the same first in the observations can only be satisfactorily represented on the assumption that the orbit is an eilligae, with a period not exceeding 18 years, in which case the perhelion distance comes out 151 million miles As the inclination of the orbit is only 20 degrees, and the comer's motion is "direct," it is not milkely that it may prove to line a short period, for the orbits of all the known short-period comets show these characteristies. This cannot be settled, however, until the comet has been under observation for a month or two

As is usually the case, the ephemerides of the camer's bortons which have so far been published "trun out" before the date at which these words will be published. In the case of Neujanin's comet, whose apparent motion is nearly uniform, the ephemeric can easily enough be extended, showing that on October 1st it will be nearly 10.28 hours 35 minutes right ascension, and 9 degrees north declination, and will be moving 45 seconds westward and 28 minutes northward per day. This comet should then be a little brighter than at the time of discovery, but as it was then of magnitude 11.5 it will not be at all considerance, even in a tele-

cope of moderate size

Metcuif's count has been rapidly approaching the Earth during the last weeks, and its apparent motion in the beavens has been at a steadily increasing This makes it more difficult to ex trapolate its position beyond the end of the published ephemeris; but it can at least be said that at the beginning of Oc-tober the comet will be in Cephens, in about I bour 20 minutes right ascension and 79 degrees north declination. On October 3rd It should be close to y Cephel, and moving to the illication of a Cephel, at the rate of fully 2 degrees a day. this time it will be about as near the Earth as it will ever get—some 54 milition miles away-and should oppear a little fainter time the seventh magnitude, conspterious in a small telescope, and visible with a good field-glass

The two accompanying sketches show the orbits of these comes. In the case of Nendanha's counst, the plane of the orbit is mear remain to that of the Earth's orbit to permit both to be drawn "in plan" without serious error. If the Earth's orbit is supposed to be exactly in the plane of the super life comes orbit must be hong-lised to rise slightly above this at the upper part of the figure, and to poss island to provide the profit of the figure, and to poss latent the state of the figure of the figure of the possible of the Earth and counted in intervals of a month are shown connected by dotped lines. At the last

hite represented (January 22nd, 1914) the distance of the contet above the plane of the paper is about haif the radius of the Earth's orbit. It will easily be seen how the comet will remain visible for several months, at first remaining in almost the same longitude (referred

Orbit of Metcalf's comet.

Orbit of Neujmin's comet.

to the ecliptic), but slowly moving northward in the sky, and varying very little in distance from the Earth or in brightness; and that later it will retorgade in lougitude, recede from the Earth, and grow father, but will remain whible in the evening sky for many months. In the case of Metcail's counct, the inclination of the orbit is much greater, and one diagram shows the councies orbit in plan, but the Earth's orbit is seen obliquely and foreshortened. From a circle's into 'asallipse whose upper side man't be supposed to be 'bihind the plans of the paper. Here, on account of biretrograde motion of the count, the threusestances are very different. The two looks approach mas essection very rapidly during September, pass one sanction eatily in October, and recode from one another with almost equal speed, so that by Documber Lat they will be about 150 million miles spart.

The conset apparent motion, in consequence of this, was also when first discovered, nince it was coming mently straight toward us; increased very ragidity, reaching a maximum seril; in October, and will then quickly fall off again, with its brightness varies to just the same way. It may finally be observed that both of these comeds have happened to present themselves under almost the most tavership conditions for observation, passing the points where their orbit comes generate to that of the Zarth at amost the same time that the Zarth at content of the conditions of the conditions

If Nonjmin's conset had come to perihelion six months earlier or later, when the Earth was on the opposite side of its orbit, it would have been fully 200 million miles from the Earth, and almost behind the Sun, and it would have almost certainly escaped discovery. Metcalf's conset, on account of its retrograde motion, would have stood a better chance of discovery, but would not have been nearly as bright as it will actually appear.

Our map shows the aspect of the evening sities so well that little description is necessary. The Great Bear is low on the northern horizon, with the Dragon and the Little Bear above. Berquies is setting in the northest, with tyra and Cypmus at a higher sittlede, and Aquila farther to the south. Peganus is just south of the senith. Below it, Erdanus, Cetna, Aquarius and Capricornus fill a wast duil region, sweeping right across the beavens from east to week, in which the only conspicuous stars are \$\phi\$ Cetl and (farther south) Fumsi-haut in the Southern Fish.

The eastern sky is far more brilliant. Arise and Tanus are high above the horizon, when Orion is rising, and in the northeast we find Andromeda close to the senith, then Perseus and Auriga, while Gemini is beginning to appear.

Metcalfs comet le in Cepheus, above the Pole, and Neumin's is a little south of the lower edge of the great square of Pegasus, so that both are excellently placed for observation.

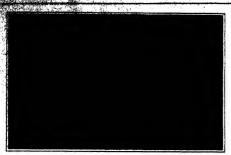

The Planets.

Mercury is an evening star throughout October, but is very far south, and hard to see. He may perhaps be picked up near the and of the month, when he sets about 5:50 P. M., but even this is only 55 minutes after sunset. Venus is a morning star in Leo and Virgo, rising at 3:20 A. M. on the

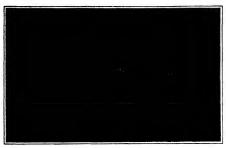

and Virgo, rising at 3 220 A. M. on the lat and 4 236 on the 31st. The change in her appearance is mainly due to her southward motion, but partly to her diminished distance from the Sun. Telescopically, she appears gibbons, like the Moon three or four days from the full. Mars is in Gemini, moving slowly eastward, and steedily growing brighter. He is in quadrature with the Sun on the 2nd, and crosses the meridian at 6 A. M. but being so far north her lesse long before midnight; in fact, by half-past 10. At the end of the month he rises shout 0 230, and is conspicuous in the latter part of the section, looking as bright as Capella or Saturn. Jupiter 3º evening star in Sagittarias and passes through quadrature on the 2nd. Seing very far south, he sets at 10:30 P. M. at the beginning of the month and 8:50 at its close. Saturn is in the eastern part of Taurus, and rises about 8:15 P. M. in the middle of the month. Uranux is in Capellacian, and crosses the meridian about 7 P. M. Neptune is on the boxeler of Geminia and Cancer, and souths about 6:20 A. M. The Moon is in the first quarter at 6 P. M. on the 28th, and fatthest away on the 12th. Sike is in continued, and new at 10 A. M. on the 28th, and fatthest away on the 12th. Sike is in continued the way on the 12th. Sike is in continued the way on the 12th. NIGHT SKY: OCTOBER-AND NOVEMBER.

One of the newer American cyclecars.

# Cyclecars—American and Foreign

#### An Automobile That Developed from the Motorcycle

IN England, and, to a recommendation a lively intorest in the "cyclecar." These little vehicles are neither real automobiles in the usual sense of the word nor matercycles. Americans, too, have developed cycle-cars of their own, or vehicles so closely akin to the typical cyclecur that they must be classed as such.

In the broadest possible sense, the American cycle-cars might be classed as imitations of the foreign style. Actually, however, they are not imitations. They are original vehicles, brought out to fill in America the place that is filled shroad by the foreign cycleor. Hence, it was to be expected, in foreseing their uitimate development, that there would be vital differbetween the American and the foreign cars

Undoubtedly it was the motorcycle that furnished the inspiration for the cyclecar. Most mortorcycles will carry two persons, but hardly in comfort. Hence, to carry two persons in comfort required some other arrangement, and because of the difficulty of construct ing side cars that will stand up and that look well and afford real protection to the second passenger, as well as to the first, the cyclecar was naturally evolved.

And, quite as naturally, the typical foreign cyclecar is characteristic of the latest motorcycle whence it sprang. It is true that some of the foreign so-called cyclecars are perilously like full-fledged automobiles in

It is therefore apparent that there are few restrictions to hind the designer of a cyclecar, and yet the restrictions are sufficient to make necessary the elimination of parts that characterize the full-sized automobile. Thus, the typical foreign cyclecar is minus the usual differential mechanism and live rear axle, and as a rule has no change genr sel. In these two respects the American cyclecar, or the American vehicle that comes er to being a cyclecur as is possible with construction, is quite different from its foreign cousin In every one of four American cyclecars on the market at present there is a change goar set, shaft drive, live rear axle and a differential mechanism, all of which parts belong to the ordinary motor car. Hence, where as the foreign cyclecar is a thing apart, the American cyclecar is nothing more or less than a ministure edition of a full-sized automobile.

In the design of the typical foreign cyclecur the motorevole motor, designed and built for the motorcycle.

is adopted in toto without any excuse and with less As a rule, it is a twin-cylinder air-cooled motor. In every one of the four American cyclecars to which we have referred, however, the motor is a fourcylinder machine and is cooled by water. All of them, except one, are block-cast machines with puppor-valves, and the one exception has a piston-valve motor. Among nty-two makes of well known foreign cyclecurs, on the other hand, only two have four-cylinder, waterthe other hand, only two have four-cylinder, water-cooled motors, whereas eleven have two-cylinder, and cooled motors, two have single-cylinder, air-cooled mo-tors, and seven have two-cylinder water-cooled motors. The resemblance to motorcycle practice is unmistak-

In the transmission elements of the twenty-two for-eign cyclecars, the resemblance to motorcycle constru-tion is even more apparent. Seven of them are driven by means of belts to the rear wheels; of these seven, six have chain transmis tershaft; three of them are driven directly by chains and the remainder have shaft drive to either bevel or worm gearing on the rear axle. In the four American evelecars which we have studied we find that set to a differential-bevel driven rear axle. The American cars, therefore, are much more clo their larger brothers of the automobile world linn are

If we examine the sixteen cyclecars representing England, France and Germany that ran in the Auto-mobile Club of France's Grand Prix race for cyclecars a few weeks since we discover that no less than nine of them were driven by belt, and of these nine six had chain drive to a countershaft; the remaining three out of the nine had, in two cases, shaft drive to the countershaft, and in the third case—the "Bedelia"—the drive was direct from the engine to the road who by belt. These little machines are very obviously nothing more than enlarged motorcycles.

Still further examination of these foreign cyclecars shows that in a great many cases the steering gear consists of nothing more complicated than a couple of steel cables running over a drum on the lower end of the steering column. Six of the cyclecars in the Grand Prix race were so controlled. American practice, however, prescribes the regulation worm and sector gear found on full-sized automobiles. Again, the trend, or

wheel track of the typical foreign cyclecur is untrower than the standard fifty-six inches milered to by the makers of large motor curs. The trend of two of the American cyclecurs mensures thirly seven and forty-four inches, respectively; of the other two, fifty six inches The average wheelbase of the foreign cyclecus is proximately eighty-eight inches, and the average wheelbase of the four American cyclecars is almost-four inches, the average weight of the foreign cyclecar is a little over six hundred and ten pounds, and the aver age weight of the four American cars is nearer to eight hundred rounds

Before going any further it is necessary to call attention to the fact. If that fact has not already been disd, that the four American curs which have been partially described, are not, strictly speaking, cyclecurs,

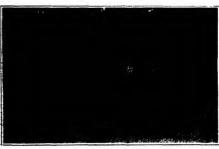

But they are small curs -very small ones and they are the neurest upproach to the true exclosur that has us yet been produced for the market in America sequently, as such, they are interesting

If they are considered as real cyclecars, they are easily the superior of the average foreign cyclecar, which in the hugange of a well known British engineer the recently paid a visit to the United States, "Is poorly designed and improperly constructed with too little attention puld to detail and to the strength of parts."

Just how for short of their ideals foreign manufacof cyclecurs have fatten is well indicated by the list prices that are quoted for these little vehicles spite the light construction, the adoption of existing motors and the incorporation of motorcycle features, all of which logically should be expected to lower production cost und hence selling price, the foreign £100 evelecar is still practiculty miknown; and it was the cyclecar that designers first sought, and, be it added, still are seeking

In the mean time, American designers have be themselves and netually have produced the \$500 cyclecar In two cases that flare includes a reasonable amount of equipment, which is never included under foreign selling prices. Starting virtually at the bottom, with little but the germ of the cyclecar idea, American designers have cast out motorcycle practice as unsultable and have built their cyclecars from the bottom up. As a result they may be styled, without any fear of contradiction, able tittle cars capable of standing up under hard service.

A French cyclecar of the tandem type.

Interesting Uses of Paper

I't is a question whether there is an industry in this country more interesting than the manufacture of wood pulp and its many uses. A number of countri have contended for the honor of enjoying greatest prog ress in the making of various articles from wood pulp. Germany, France, Eugland, and the United States are the principal chalmants. Of the four countries named Germany would seem to have the balance of testimony on its side. Noveltles made from paper pulp are by no means of rare occurrence in the 1-nited States, and are now so multifurious as to defy enumeration

At first, wood putp was used entirely to making pape but to-day it is employed for menifold purposes use bids fair to be birge for moldings, friction clutche helt-pulleys, genr wheels, burrels (reinforced with wire), tubs, palls, washboards, water pipes, conduits, caskets, buth tubs, curriage bodies, floor covering, electric insulators, umbrella stands, furniture, imitation of leather, cloth, and silk. Clearly the employment of wood pulp is practically unlimited.

The great consumers of wood pulp to-day are the paper manufacturers who use nearly 90 per cent of the entire production. According to the Bureau of Statisties, there are nt present about 250 mills which manufacture wood pulp in this country. The enpacity of these mills is over 2.500,000 tons of pulp manually, valued at more than \$32,000,000. In addition to this amount, more than 400,000 tons are imported from Canada and various countries of Europe. The value of material received from abroad in 1911 was nearly \$15,000,000 These flures show an increase in the business of over five hundred per cent in the past ter years, and the same time in the future promises even

By proper treatment wood putp can be made perfeetly translucent, unbreakable, and indifferent to at-mospheric changes. While it has not yet been made transparent, it admits abandant, soft, pleasant light, where it is used in place of window panes. Paper pulp is now made up into boards that can be used in a variety of places to supplant the use of wood ease of molding into any desired shape and the saving in weight make the use of this product valuable in struction of the ornamentation of ships such as the facing and frames of doors, walnesotings, panels, etc. This material is also used in making imitation tiling for the walls of bathrooms, the forming of closet seatetc. In fact, entire houses, garages, hencoops, etc., have successfully been made of this paper board. When properly impregnated it is impervious to moisture and forms a good non-conductor of heat. Another product used in house construction is roofing tiles, which are now gaining a reputation for their smeerior qualities over other rooting uniterial in the market. The application of wood pulp for house building is not new, and has met with complete success. In Europe there are rms which build houses almost entirely of water priofed postebourd. Wood pulp is likewise used in wood for making furniture, tables and fold ing chairs, their chief advantages being lightness

ing charts, their circum total anges being ingamess.

Paper serves are now being unde which give therough satisfaction. The principle of having wood against wood is a point in favor of wood servess. They are used for ornameural work, where it is destrable to give the heads of the screws the same color and grain A varulsh on top of this udds to the offect and protects the dye, as it penetrates the fiber and acts as a preservative—It has been estimated that these wood buln screws can be made so cheaply as to compete successfully with screws and log bolts of other Paper screws can be readily removed even after they have been in place for many years. The screw are cast and the thread is cut as in the common wood screws. The drive screw is east with attenuated through curves, so that when delven it revolves and finds a firm footing in the wood. It can be driven only into soft wood after a hole is first started

Another economic application of paper which is gaining in importance is the making of cord and rope. These new ropes are spin and twisted out of the thin threads which are made from wood pulp. This in-dustry has attained considerable importance in Europe It is said that these ligneous fiber ropes are used m or less extensively in the foundries of Germany. fine threads which make no these ropes are made by forcing the chemically treated wood pulp or cellulthrough very fine tubes into running water, in which they harden. After they are dry they are perfectly pliable and somewhat clostic, and may be spun or twisted into any form whatsoever. These minute elongated threads are caught up as they are forced through the fine tubes and spun into ordinary slikes threads, which are woven into a fabric resembling

A French inventor discovered that paper may be eninto narrow strips several millimeters wide and that after these have been steeped in certain chemicals which give them tenecity and ducillity, they may be rolled and twisted into threads, which may be worked

up into fabrics of various kinds and put to a great variety of uses. Another French chemist has discovered a way to make such fabrics, as well as ordinary paper. erproof, and a German inventor has p quality of thin paper practically fireproof.

Such discoveries have ied to the making of hats, incounts, corsets, vests, underwear, collars, ties, secks, shoes and even overshoes. In the Chicage City Hos-pital experiments have been made in furnishing the patients with garments made of a soft tough paper These garments are light and airy. After use each garment is destroyed and lius all danger of infection The paper raincoat is a nevelty. made of a light-weight waterproof paper. The garment comes folded in a very small package which can easily be put into a lady's handbag. The package is ed and the coat unfoided as occasion de article is so cheap that it can be thrown away after use. One inventor has designed a paper sock for use in the army. The sock covers only the parts of the foot that are usually chafed by the shoe. This insures light weight and adds greatly to the comfort of the

Paper may even be so treated as to make it suitable or sails for light vessels. Such sails are not woren for sails for light ves from sirands or threads, but are made up from com d sheets of paper, which are made in th way, the pulp having been thoroughly mixed with cer-tain chemicals and other substances. These paper sails are inexpensive compared with good canvas stock or

But hy far the greatest progress has been made in the application of this material to sanitary and domes-tic uses. The realization by the public generally of term theory of disease has do e more to multiply s of paper than any other factor It has led to the introduction of the various individual recentacles and containers that now appear upon the market. Notable among these is the individual drinking cun. The extent to which those cups are utilized can be com-prehended when it is stated that the returns routized from the sale of penny cups from slot machines in the Pennsylvania State capitol indiding alone amounted to \$113 during the past year

In modern sanitation and the treatment of diseases the various paper receptacles and protective appliances have proven of inestimable value. In some of the west-ern States, notably California and Colorado, which furd a climate especially beneficial in the treat tuberculosis, it has become imperative for all public urities to be thoroughly protected. Otherwise cen-tugious diseases will be spread instead of checked. Some of the most dangerous articles are the telephone mouthpiece, the common towel, and the public drink ing cup. Paper has come to the rescue and supplied towels and drinking cups that are to be discarded after

Milk bottles of paper will soon be in extensive use. They are cheap and saultary and the troublesome washing and collection of the empty bottles is obvinted. The danger of breakage is also eliminated. A very recent improvement in paper milk bottles appears in a patent to A G. Brant (No 1,067,237). This is a bottle having a narrow strip of transparent material running the full length of the side. This allows the buyer to the level of the cream on the milk or the level of the liquid in the interior, and enables him to whether there is any sediment in the bottom of the

Paper recentacles of all kinds are now on the market. These are especially valuable in the packing and shipping of foodstuffs. The manufacture of water- and gream-proof paper has recently been introduced and is especially useful in this connection. Eggs are best packed in paper receptacles, and a recent practice has urisen of shipping eggs by parcels post in a special type of paper container Ice cream is at present sold in small quantities, packed in paper receptacies, and it has become a practice for some of the progressive dealers to furnish therewith cheap paper spoons that cost very little.

packing of loayes of bread in individual wrag pers is another advance in the handling of foodstuffs, an advance which not only insures cleanliness, but also prevents the entry and escape of moisture and preserves the freshness of the loaf.

One inventor, J W. Welss (No. 1,063,845), makes a collapsible flox of paper with a reinforced part along the sides or corners. Usually collapsible paper boxes are very flimsy, but this box is strong enough to bear the weight of a full-grown man. The immensity of the paper box industry may be restized when it is stated that in one industry alone—the manufacture of pens pencils, and erasers—over four thousand different sizes

pencies, and erasers—over four thousand different sizes and sinapse of boxes are required. But the use of paper in this country caused approach the many uses to which it is put in Japac, which is virtually a paper kingdom. The houses are made of virtually a paper kingdom. The houses are made of the light frames of hamboo covered with paper. Almost overything that the Americans make of wood or leather

in there made of paper. The ed rainy or snowy weather made of a very tengh er-of waterproof paper. These mantles can be used of thoughly for about a year and cost only 18 cents. ? consequence for a year and cost only 18 forms. The less merchants use raper suchs, the paper having been chanced by a vegetable soid. These suchs are used over and over again, and it is said to be a common chiag to see sector that are eight or ten years old and have paper patches on them. The

SEVENDERATE RANALOW GRISSERENAE

#### The Wreck of the First German Naval Airship "L 1" By Carl Dienath

THE Zeppelin "L 1," the first attempt to adapt a Tairigible I dirigible to regular sea service with the navy, foundered in a heavy storm on the North Sea with great less of life, twenty nautical miles to the northwest of Heligoland, late in the afternoon of Sep 9th. It left the air harbor of Hamburg at 1:30 P. M. right sunshine to take part in the night man of the navy, with supplies and a crew for a thirty-house The ship had been in service for nearly one year, making more frequent trips than any airship of the army, and it had been found desirable to equip il with a heavier and more powerful wireless telegraph, stronger electric searchlight (big are lamp worked by heavy storage batteries), with a sound-proof cabin for the wireless apparatus, with an upper platform accom modating two machine guns in place of one; all being an additional load, for which the ship's original carrying capacity was not quile sufficient. It meant that at the start of a long trip with great quantities of supplies, and with a numerous crew, on duty in two shifts or "watches," the surplus lift for emergencies was smaller than originally provided for. The ship had en built with a greater displacement than the old type for over-sen use. Its unfortunate commander, who, a naval captula, did not survive his ship, is known to have privately stated, from experience, that the mixes had made it too heavy, and that it might plunge down some day.

s of the naval authorities to test and develop military equipment, and the fact that even so, only the extra amount of buoyancy provided for oversea use had been sacrificed, and what on a smaller "overland" dirigible would have appeared a fair amount allast could still be carried, is responsible for this peculiar situation, which, through an unusual combina-

On the day of the wreck the "L1" started fully influted, but in bright supshine, losing immediately gas by expansion As soon as the sea was reached the sun disappeared and it began to rain The gas shrank and the hull became heavy with moisture.

id lieligoland the nirship was struck by the first real sea storm ever encountered by any niveraft was one of the typical flerce storms on the North Sea, which at this time of the year, according to Capt. which at this time of the year, according to Capt. Blew of the alrebip "Weterla Ludse," formerly a navil officer and very familiar with the German Ocean, mostly prevail at the latitude of Norwae, but may with-out warning extend farther south. The rain squali-lecame of truplent violence and vertical gasts threw the alrebit up, and down nearly a thousand feet at a . The cooling of the gas became so intense, and the so heavy with the water streaming from its sid not to mention the downward momentum of the imping-ing tropical rain, that Dr. Eckener, the experienced pilot of Zeppelin dirigibles, figures a loss of bnovancy that meant the sacrifice not only of all the avai bailast-the gasoline, unfortunately, could not be quickly osinst—the gasonine, unfortunately, could not be quickly discharged—but also all the aeropiane lift of the inil and the propellers. This left nothing with which to counteract the vertical gusts. When it was tried to "beach" the sirship by running at top speed before the wind, the effect of the vertical gusts (according to Cant. Biew's experience in running before the wine creased so much that the ship became their toy. With the heavy storage battery screwed to the front car, and very probably a rush of the crew at the last moment servers, most of which were kept the life-ore the vertical radder could not prevent it quickly enough from siriking the raging sea head on while traveling at a terrific speed, thus burying and crushing the bows and stunning every man in front. The hull crashed flown on the car. The waves made such short work of the buil that every single ses compartment was soon torn by the broken aluminium frame. The wreckage at down in forty minutes. The storm, which lasted all night, was so had that the fishing steamer ran great risk trying to save some of the crew.

The new naval airship just completed is provided not

any new may a arrang pass composed as provided not call with great surglus life and much higher speed and controlling power, but is also stouter and shorter, thus expressing proportionally less entrace to the rain. It is needless to say that any other type of airwark tweld have shared the fate of "L1" under like conditions.

#### The Largest Ice Cave in the World

A FEW years ago some members of the Austrian Speleological Society discovered in the lackatefu mountains some caverns which are among the largest in Europe. One of these grottoes, the lougitudinal axis of which is fully 6,809 feet long, moreover turned out to offer additional interest by the truly enormous ice masses and was found to be the largest known tee cave in the world.

Though a scorching ann may be burning outside on the bare mountain rock, there is always an key wind blowing through this underworld, freeding everything within the reach. Only sometimes, when the outside temperature ranges between 32 and 41 dag. Cent., and a comparatively warm rain pentrates through the fiscures of the rock, entering right into the cavern, will there be a temporary cain and distinct meiting of the ice.

The Dachstein ice cave comprises several domes filled with ice, which com-municate with one another through a number of frozen gaileries. An icc crevice 89 feet deep and 116 feet in width traverses the floor of the cavern 165 feet from the entrance. Gigantic ice pillars were found to tower on both edges of this chasm, in the depth of which there unfolds a fairy-like ice scenery. Beyond the abyas the cavern widens out into a mighty dome ("Tristan Dome" as it is called), where a plain ice sheet reaches from one wall to the other, carrying ice stalagmites of the most fantastic shapes. This hall is continued in a gallery through which flows an ice river A hall of imposing di-mensions (390 feet in length, 231 feet in width and 116 feet in height), called "Parsival Home," is next entered quite shruptly, which exhibits an immense va-riety of ice formations of every description The descent to the bottom of the cave is made over an ice river, known as Montanivasch Glacier At the foot of the glacier a lake of ice spreads from end to end of the hall, carrying ice stalagmites of animal likeness. Over an ice wall 50 feet deep and through a portal formed by huge ice arches, access may be had to ond part of this underground This is distinguished from the second part world. former by a considerably higher temp ture, preventing the formation of ice. Tremendous rocky deserts with an enor-mous chaos of boulders here take the piace of greenish shining ice domes. The largest room is "King Arthur's Dome," a cally central hall, 660 feet long, 330 practically central hall, 6 wide and 100 feet high. Its huge side galleries contain, in addition to stalagmites of cauliflower shape, an enormous mass of crystalline erratic blocks brought down to these depths from the Central Alps by the underground rivers of an early geological period.

#### A Bridge Within a Bridge

A NEW \$600,000 steel bridge has been with the Taxon over the bay to open up the tide flats to industrial concerns. While the new bridge was being built, the old bridge senanted to service and the accomplishing photograph shows the two bridges, due above the other, the old beinge new yet yet removed at the time the

Buttresses of an elm tree.

The Dachstein cavern; Parsival Dome, showing the ice lake.

Automobile searchlight for the French army.

New vertical lift bridge built over a swing draw.

picture was taken. The new bridge clears the water at high tude by 90 feet, while the lift span when raised provides a clearance of 135 feet, the lighest point of the structure being 175 feet above the water. The vertical lift weights 800 tons and is supported by two 400-ton concrete counterweights. The lift is raised and lowered by cleertricity. The bridge, including wooden approaches, has a total length of 3,000 feet, of whell 2,100 feet is of steel. The lift span is 220 feet long and 70 feet wide, providing a road-way 50 feet wide with sidewalks ten foot within a road-way 50 feet wide.

#### A Curious Elm Tree in Florida

THE necompanying photograph shows the base of an elm tree, which was standing on the banks of the Dklawaha, near Silver Springs, Floride. The inter-esting features of this tree, well illustrated in the photograph, are the high buttress roots at the base of the trunk. tresses are plank-like outgrowths not more tresses are pinna-tike outgrowths not more than an inch or two thick, extending 6 or 8 feet outward, and about 5 feet upward along the stem. These neted as stays or props to preserve the upright position of the tree, which grows in wet shallow soil underlaid with hardpan. They are a comman occurrence in many tropical trees, which, as a rule, have tall straight trunks with the branches and leaves only at the top, and, therefore, require some support us is offered by these buttress roots. Such "spurs," as they are often called, are commonly seen in large mahogany, Spanish cedar, and cellu trees in tropleal America, hat it is very unusual to find trees from the temperate clumate with such pro-nounced buttress development. This curions elm tree was found a number of years ago, but recently it had to be cut down on account of certain improvements. The stump was dag up and removed to a more accessible place, for the benefit of the many tourists who visit Silver Springs

#### Automobile Searchlight for the French Army

URING the maneuvers of the French Darmy in the Southwest, which began on September 17th, a searchlight automo bile was used; that is, an automobile with blie wire used; that is, an automobile with a powerful searchlight suitably mounted at the rear of the body. The swivel stand-ard of the searchlight is clamped to a plate which is yieldingly supported between coll springs carried on bolts. This prevents jars from being communicated to the searchlight when the machine is in motion. To steady the searchlight while In transit, it is held by four guy cables, the two forward ones being uttached to coll springs so as to absorb shocks. The searchlight will project a powerful beam to a distance of three kilometers (1.86 miles) The automobile carries a tripod on which the standard of the searchlight may be clamped at a moment's notice when desired

#### The Pseudo-language of Monkeys

CONCERNING the supposed language of nuthropoid upes, Prof. Boutan has recently taken up the question and arrives at a negative result. It will be remem-bered that Dr. Garnier came to the conclusion that monkeys have a language analogous to human language and express themselves by signs as well as by sounds which they emit - According to Prof. Bontan, there is only a difference of degree between this and laman speech and not one of kind. He observed the sounds made by a gibbon which he had captured when young, and his experiments cover more than five years. He finds that the animal can produce only spontaneous and instinctive sounds corresponding to a state of satisfaction or the like, or again to a stale of uneasiness or feat, also great exeltement, and the sounds do not appear to correspond to a real language, but rather to what he calls "pseudo-language."
While sounds of real language are acquired by education, those of pseudo-lan guage are purely spontaneous, and he thus differs from Dr. Garnier's conclusions.

#### A New Type of Spiral Gear Differential

Of the many parts of the motor vehicle, it is doubtful if any has been given less attention than the differential mechanism. The device is pulpally im-perfect and long has been viewed in the light of a necessary evil. It is not fully light of a necessary evil. It is not full automatic in action, or rather it does no automatically accommodate itself to the requirements of the car under certain nditions that are fairly common. instance, it does not proportion the driv ing effort of the engine according to the iraction obtainable at the driving and it is for this reason alone that a number of maunfacturers of commercia vehicles have equipped their products

Spiral gear differential.

with devices to throw the differential out of action temporarily

With the device that is shown by the accompanying illustration all the disad vantages of the orthodox type of spur goar differential seem to have been eliminated It is a new type of differentia differing from anything else of its kind Instead of the usual spur gears, the dif ferential gears are of the spiral type Because of their shape the action of the chanism is different from the action of the familiar differential. The master driving gear remains of the bevel type, as may be seen by the picture.

Owing to the shape of the spiral gear teeth, those that are anchored to the drive themselves. It follows, therefore, that while the vehicle is moving in a stratght line the whole mechanism is virtually locked -- insofar as the drive from the engine is concerned -- and the axle ro-tutes as a solid one. If one wheel should encounter slippery roadway and lose truc-tion, all the drive then automatically would be taken by the wheel on dry mave

ment where traction was undisturbed.

When the vehicle rounds a curve, how ever, the spiral gears are driven by the road wheels, thus permitting, or rather eausing, a differential action similar to the action caused by the ordinary spur gear differential. There is this important ee between the action of the spiral gear differential and the other: The usual type of differential is governed in action by both the distance traveled by the wheels and the traction obtainable by the wheels separately, whereas the spiral gear differential is numflected by the traction obtainable, and its action is governed sole ly by the distance traveled to the wheels

The new gear is the same size as the ordinary type of differential mechanism, for which it can easily be substituted, the operation requiring not more than one our, where the driving axles are of the full floating type. That it is not more difficult to manufacture than is the ordi-

nary differential is made plain by the fact of rock, but is reached by passing the pixel that six of the spiral gears are identical through chinks in the broken work walk. that six of the spiral gears are identical and are of standard size and shape; two other spiral gears are identical; and the honsing is exactly the same as the usual spur gear differential housing. two kinds of spiral gears are siike, only two settings of the gear cutting machintwo settings or the gear cutting macani-ery are necessary, whereas each gear in the spur gear differential must be cut sep-arately. Incidentally, for the ordinary 80 rse-power car, it is pointed out by the makers, some 72 gear teeth must be cut for a spur gear, whereas with the spiral mechanism the number is reduced to 54.

#### Apparatus for Testing Mine Gase By Frank C. Perkins

NOVEL apparatus for testing min-A gases is shown in the accompanying illustrations. It consists of a small braspump by which gases are pumped through an extension pipe to a Wolf testing lamp The percentage of hiflammable gas intro duced into the combustion chamber of the tamp by means of the pump may be de termined by noting the appearance of the tip and the height of the fiame. The gus is introduced into the lamp in very small quantities just sufficient to affect the character of the flame without danger of an explosion. With this apparatus it is possible to detect the presence of dangerons gases even when they are not pres ent in sufficient quantities to cause actua explosion. When examining old working places where the roof is badly caved and

dangerous it frequently happens that the inspection is not as therough as it should

be because of the danger of entering

fire-boss may stand in a place of safety and obtain his sam ple of the atmosphere by using a long ex-tension tube. A few strokes of the pump will be sufficient to draw a sample of the atmosphere into the safety lamp, into which the gas is forced by the nump. The accompanying operator testing the atmosphere in a chamber thirty feet away, which has been cut off by a fail

ever, the operator or

Mine testing apparatus.

#### Novel Multiple Drill Head for Roller Bearings

ONE factory has circumvented a troublesome problem in machine design by a special multiple drill head. It was proposed to design a drill head which would drill eleven 0.255 inch roller seats aced equidistantly on a 1% inch circle The comparatively large size of the seat on this small circle rendered the spacing of adjacent holes so extremely close that it was considered impractical to drill the eleven seats in one operation and at the same time retain a sufficiently strong spindle construction to make the head practical. With an ordinary multiple delli head the roller cage with eleven holes could not be drilled in two operations, and therefore the head was designed for do ing the work in three operations, but working simultaneously on three roller cages. The result of this design is a multiple drill head for attachment to an automatic dial feed drilling machine,

The head is attached to and driven by the automatic drill press having a turret indexing table containing twelve chucking stations evenly spaced on a 9.6-inch circle, in which table twelve cages to be drilled are placed at the same time. The drill head contains three sets of spir two having five drills each and the third one drill, located on a radius corresponding to the chucking stations of the index-

With the turret containing twelve case the drill head is given its first plunge, drilling five holes in the first cage, five in of the danger of entering the second, and one hole in the third.
With this apparatus, how-

one twelfth of s the first cage under second group of spindles, the second under the third spin dle and a new cage under the first group the three operations are carried on successively until one although three cages are operated on at the same time. While these operations are in progress the operator has ample time to remove the completed cares as they

ome out from under the drills and to in-

Each of the three sets of spin provided with a receding pliot which enthe drills and forces them into preper alignment. The receding pilots for the second and third spindles have locating pins which enter the holes already drilled and register accurately the spacing of the holes remaining to be drilled.

## An Unusual Type of Tire Inflater W ITH the growing tendency of auto-mobile manufacturers to fit their products out with complete equipment, inuding a great many devi-

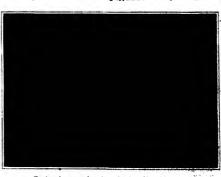

one time were viewed in the light of "extras" and paid for as such, greater attention is centering upon the necessity for power tire inflators. Of the several that have recently been placed on the market that shown by the accompanying illustration is unique in that it is the first to em-ploy the diaphragm principle so well

known in hydraulic pumps.

Needless to point out—for the part se
tional picture makes that fact plain has no piston nor has it a cylinds word is usually understood. For these reasons the minimum of attention during operation (which means lubrication) is required. As there is no opening betw the "crankshaft" if such the eccentric that drives the member attached to the dispuragm may be termed, it is at impossible for oil or oily paper to be dis-charged into the tire. The air chamber and the crankcase are quite independent in fact, and the former is perfectly by the rubber disphragm.

#### Fire Sprinklers-A Correction

I No or jesses of September 18th. we pub-lished in article on electrical fire pro-tection degices which requires correction. It was the way of the second of the con-traction of the contraction of the con-ceptance of the contraction of the con-section of the contraction of the con-section of the contraction of the con-section of the contraction of the con-traction of the contraction of the contraction of the con-traction of the contraction of the contraction of the contraction of the con-traction of the contraction of t ure is too nigh. The proper cost of spring-ler work, we are assured, varies between \$5 and \$10 per head. So, too, the state-ment that a one hundred thousand dollar factory could be protected only at the exnditure of \$20,000 is in error. We are formed that a \$100,000 factory could informed that a \$100,000 ractory count probably be protected for \$6,000. These corrections are made because it was our intention in the article referred to, to call attention to the merits of the sprinkler system, which indeed the article did

#### How the Government Tests Paper (Concluded from page 260.)

cure sufficient and representative samples for slight differences in materials and proes of manufacture may affect the general run.

The next test is to determine the thick-ness of the sheets or the bulk. With limit-ed space in both public and private librarles a demand has arisen for less bulky books, and consequently thinner paper and to-day it is considered the best practice to employ a paper of better quality of material, but of less bulk. The roughest test for thickness is to take or fold to gether a certain known number of sheets and then measure their tilickness with a rule or more usually with a caliper rule increused accuracy is secured by the us of some form of calipers for the single sheets, while for the most refined measure ments a micrometer gage that may be read to 1/1,000 or better 1/10,000 of an luch is employed. This is an ordinar; form of screw micrometer, but care mus be taken to secure an even and constant sure, and the average of a number of readings, at least five, should be taken rendings, at least nvc, snound be taken There are also direct-rending micrometer thickness testers, and one of these used at the Bureau of Standards is shown.

#### Ascertaining the Strength of a Sample.

Strength is the next important consideration, and is one of the more usual cration, and is one of the more usual commercial tests to which paper is sub-jected. In the ordinary American strength tester, usually the Mullen type, a sample of paper is changed about a circular opening one square incit in area, below which there is a rubber diaphragm. By means of a hand wheel the pressure of a liquid

true as it corresponds more closely with the mean strength or the strength in the cross direction. With this machine the application of the pressure by the manipu-lation of the wheel and other conditions can effect the rendings, so that the same

It is also desirable to ascertain the ten sile or breaking strength as well as the bursting strength, and for this use is made of a German machine, the Schopper strip tester, in which the weight remired to is automatically recorded and the amount of stretch before rupture. This test is the approved one in Europe for strength. and in recent United States specification tests with the Schopper machine are spe cified, though a corresponding test on the Mullen machine is given for the benefit of manufacturers not supplied with the German apparatus. A strip 15 millimeters in width and 180 millimeters long is taken, which is clamped at efther end and the tension is applied with a piston and cylinder. In this test strips both with and against the grain of the paper are used and information is gained by the two sets of tests as to the structure of the paper. The German method is to state the strength of a given sample in

state the strength of a given sample in terms of the length required to break it when suspended by one of its ends. The test for endurance comes in meas-uring resistance to folding, which test takes the place of the former rough crump ling test where a square sample of the paper was taken, crumpled up in the hand, noothed out, and then crumple opposite direction, repeating the process and observing the number of minute holes formed along the creases. The folding test is very important as determining the on in dispiraging is increased infill the durability as the greatest wear comes paper is suptured, the number of pounds where a wheet is folded in hinding in a pressure being indicated by an accurately book or pamphile or in the case of a calibrated gage. The bursting pressure, map, bond, or legal document, that must the average of ten readings, is assumed to represent the mean strength or the average of the strength across and length—planted by the folding anachies, which is wise of the sheet, but this is not strictly—planted by the folding anachies, which is

## ORIENT-INDIA

by S. S. CLEVELAND (17,-000 tons) from New York Jan. 15th, 1914. Through the Mediterranean, Suez Canal, Red Sea and Indian Ocean, to Bombay and Colombo. Side trips through India, Holy Land and Egypt. Stopping at points in Europe, Asia and Africa.

Duration 93 days. Cost \$700 up. Including shore excursions and necessary expenses.

# WEST INDIES PANAMA CANAL

by S. S. Amerika (22,500 tons) and Victoria Luise (17,000 tons) during January, February, March and April. Duration 16 to 29 days. Cost \$145-\$175 up. Also two 15-day Cruises from New Orleans during January and February by special cruising steamer. Shore trips optional.

#### INDEPENDENT TOURS

for 1914 arranged by our tourist department, including trans-Atlantic passage on S.S. Imperator and S.S. Vaterland — world's largest ships.

#### MEDITERRANEAN SERVICE

Regular Sailings to Mediterranean ports, also Nile Service by superb steamers of the Hamburg and Anglo American Nile Company. Sailing weekly.

#### 1915 Around the World, Through Panama Canal

From New York, January, 1915, by S. S. Cleveland (17,000 tons). Duration 125 days. Rates \$900 up, including shore trips and necessary expenses.

HAMBURG-AMERICAN

LINE 41-65 Scandmay, Now York Philadelphia Boson Pitthenen Chinge B. Lank curate and quantificative results. By many authorities it is considered the most valuable slugie test to apply to paper to determine bus probable durability in actual service. In the Schoquer folder a strip 15 millimeters wide and 05 millimeters to longth under a standard tension of 1,000 grammas is bent linet and forth repeatedly on itself, until the fibers wear through at the line of folding, and the number of double folds automatically is registered. The paper of the greatest endurance has the highest "folding number." For example in an extreme case the tim-summent specifications for the "best purchasent deed" paper require that it shall have a folding endurance in the week direction of not less than 2,000 double folds.

#### The Influence of the Atmosphere.

The expansion of paper under various atmospheric conditions is important in my printing operations, and this is tested by measuring the sheet as temperature and humidity are varied. Then there is the measure of the amount of absorption, which is determined by the height that a liquid will rise by capillary action in a given time when a strip is suspended ver tically with the lower end lumersed in water. Such a test is of course peculiarly applicable to blotting paper. cal team of paper must be carried on at a standard temperature and humidity, which, at the Bureau of Standards, is taken at the average temperature of 65 deg. F. and 65 p. c. of relative humidity, the elaborate heating and ventilating sys-tem of the bureau permitting the realiza tion and control of these conditions transparency of paper may be decided by the number of sheets which must be interposed between a standard source of light such as a 1-candlepower Heffner amyl acetate burner and an observing tele-scope to cut off the light. This, however, though meful in the case of tracing pa-pers, window envelops, etc. is a test of limited value

The testing of paper by no means ends with the physical examination. Under the microscope the kind or kinds of fiberfrom which a sample of paper is unde readily can be identified, not merely long fibered materials such as cotton, flax and hemp, which afford the most durable papers as they yield a nearly pure cellise, but others which have been to extensive chemical treatment. At the Burean of Standards microscopical ex-anination is able to indicate the correct ther contents of a sample within 5 per cent in the case of a mixture of rag and bleached chemical wood, while in the case of papers formed by combinations of phite and soda palp and contabiling ground wood a degree of accuracy well within 10 per cent has been secured special technique involving the treatment and stabiling of the fibers has been devel oped so that they readily are recognized and their relative proportions estimated

#### Analyzing "Loaded" Papers.

Chemical analysis is necessary to determine the amount of loading or white insoluble mineral matter added to paper during manufacture to improve printing qualities, increase opacity and reduce weight. In the coated papers med for fine half-tone printing this muterial may anomat to 30 per cent or more, while in other papers it varies from a minimum of til, per cent. While ossential to detail in fine half-tone printing it weakens the paper and decreases list durability. This loading is determined by its amount of which is stated in paper specifications. It is ascertained by harning a small assumpte of paper in a platinum crueble until there is no carbon in the residue, which is lien cooled in a desicutor and weighed, being subjected to analysis in case it is desired. The amount of ash thus obtained is easily less than the actual amount of loading or filler, which may contain water and other volatile agents that paiss of the burning. Chemical analysis sife overein the native of the

# A New Quality in Tobacco

Just a year ago Stag was first put on the market, and it proved an instant Sensation.

For years, smokers had been waiting and longing for the tobacco of PERFECT FLAVOR.

Stag took the wonderful Burley leaf, found new perfections in it, and gave the world a tobacco whose fragrance and flavor touched new heights.

It seemed impossible that  $\underline{any}$  to bacco could go further. But Stag  $\underline{has}$  gone further.

All smokers have known that the taste tires of any tobacco after a while. The "bloom" wears off. There's a craving for a new smoke.

The past year has shown this is NOT TRUE OF STAG.

The enhussam you feel with your first pipeful GROWS every day, every week, every month. Thousands of smokers have testified to the fact. This is whys Stag Smoker smiles when you take to him about the other tobaccost. Or he replies, in the words of the immorrant Kiping:

"When you've head of Siag a-callor," Then you don't beed rothen else."

paper suitable for printing or receiving the ink. These may consist of glue, case in, starch or rosin, and when used in unounts may affect the strength as durability of the paper. The analysis will also indicate the nature of the coloring matter used.

aper testing and analysis are at raper testing and snatysis are also ex-tensively carried on in private and com-mercial laboratories with which the Bu-reau of Standards in no way seeks to com-pets. In paper as in other industries, its services have not been confined to the Na-tional Government, but it has sought to improve and advance manufacturing and trade conditions by the formulation of oper standards and technical res In this, the paper testing laboratory in charge of Mr. Frederick C. Clark, to whom the author of the present article is under obligations for information and photo-graphs furnished, has been eminently suc-

#### Recent Improvements in the Refrigerating Industry (Concluded from page 261.)

is in the form of a liquid as when in the gameous condition. In this condenser the hot gas entering at the bottom comes in contact with the cooled liquid, gives up its heat to the liquid and become densed. The liquid thus heated rises to or part of the condenser where its heat is transferred to the cooling water when in transferred to the cooling water, When in operation the condenser is prac-tically full of the liquefied refrigerant. Of course there is always a constant flow of liquid to the expansion coil from some point in the condenser above the gas in

Important changes have also been made in the expansion or evaporating device but these changes involve the method of eration rather than the structure. Until recently the general practice was to permit the high pressure liquid refrigerant to pass into the expansion coil through ant to pass into the expansion coll through an expansion or throttling valve in the form of a spray. As it passed through the evaporator this spray was gradually con-verted into a gas by the heat absorbed from the substance to be cooled, and the compressor and recompressed. It was found, however, that by maintaining the evaporator partially filled with liquid refrigerant the cooling was much more uni form and satisfactory.

form and sansaccory.

In Fig. 4 is shown a section of a shell brine cooler of the flooded type in which the brine to be cooled is forced through the tubes by a pump. The shell is maintained practically full of liquid ammonia. the inflow being governed by a float valve as shown. The ammonia vapor produced as shown. The aumobile vajor produced by the heat of the brine is constantly drawn off at the top by the compressor. In construction and operation it is not unlike a steam boller. The heat, how-ever, is obtained from the brine flowing through the tubes instead of from com-bestion serves Abana and the combustion gases. About one tenth of the liquid ammonia flashes into vapor as it enters the cooler by reason of the reduc-tion of pressure. In the flooded type of cooler this vapor does not mass through the cooler but is led direct to the suction

In the absorption refrigerating field bu few changes have been introduced except attempts to make such machines auto matic so that they can be used for ho hold purposes. The recent discovery that ertain solids, particularly sulpho-cyanic of ammonium, could be used as the ab-sorbent in place of water, attracted much attention. This absorbent gave very flattering results as to heat efficiency, but d to be extremely corrotive, destroying the walls of the generator in a com-paratively short time. Should this diffi-culty be overcome, the absorption machine

culty be overcome, the sheorytion machine may come into more general use. Trobably the most extensive use made of artificial refrigeration is in the manufacture of tee, for except in the most increment successful to the continuous statement of artificial refrigeration is in the manufacture of tee, for except in the most increment statement of a statement of the continuous statement of the co

## Unproductive Overhead Devours Profits

The only manufacturer who has any license to try to operate a special shost-metal work department is the man who knows in advance that he can keep such a department in

ominimus operation.

80% of all privately operated departments of this class are run at a loss compared with the cost of the same work placed with

proptes the only ice available is that which comes from the local ice plant, and cically all such ice is made either by the can or plate process. In the former the cans of water are set in a tank filled ith brine which is cooled by the am-onia. The ammonia coils are usually arranged between the rows of cans, but a shell cooler, such as is shown in Fig. 4, may be employed, and the brine is circu inted through the shell and thence around isted through the snell and the caus. The brine is cooled by the ammonia and this cold brine around the caus the water therein to freeze. The brine acts merely as a heat or cold trans-ferring medium, and in addition serves as a large reserve of cold in case the compressor should be stopped for any reason. Common salt and calcium chlor-ide are used for making the brine. When all the water in a can is frozen the can is drawn out and warm water is poured over the outside until the eake is loosened and slides out, after which the can is refilled and replaced in the cold brine. In refilled and replaced in the cold brine. In the plate process a series of freezing plates are arranged side by side in a tank filled with water and the ice forms in large cakes on the sides of the plates. The wa-ter is kept in constant circulation through the tank in order that the ice may be clear. Each freezing plate is made up of a large number of connected pipes ar-ranged one above the other, through which To freeze a cake a foot thick requires about a week. case a root their requires about a week. In removing the cake a warm fluid is cir-culated through the plate until the tee is loosened and it is then lifted out and cut into pieces of convenient size.

In the ice manufacturing industry the most marked improvement has been the development of the raw water system. Should cans filled with raw water or ordimary city water be frozen without any agitation, the ice will be white or opaque, due to air bubbles and sediment frozen in due to air publies and sentment roses in the ice, and for this reason distilled wa-ter was heretofore universally used in making can ice. However, by injecting a constant stream of air into the raw water during the freezing, ice can be ob-tained as clear and pure as with dis-tilled water. To distill all the water used in a can plant is an item of some expense. and especially so where other power than a steam engine is used. Fig. 5 shows one of the latest forms of the freezing can The air is injected through the bottom of the can, which is not exposed to the cold brine. Pipes for circulating water through the can are also provided. The cans are secured in the tank and to harvest the ice the brine is warmed sufficiently to loose the cake.

Important improvements have also bee made in the freezing plates of plate ice systems. In the older forms the ice cake systems. In the older forms the ice cake was frozen on one side of the freezing plate, and as the transmission of heat through the ice is very slow, it required a number of days to freeze a cake of marketable thickness. With the apparatus shown in Fig. 6, the time of freezing can be very greatly reduced. This device conhe very greatly reduced. This device consists of a row of outer tubes closed at the top, projecting up into the tank and inclosing inner tubes open at the top. These tubes are connected with supply and return headers for the refrigerant which may be brine or liquid ammonia. In operation, the ice gradually increases in thickness around these tubes until the various masses meet and coalesce to form eserum masses meet and coalesce to form continuous cake. This cake is harvest-d by divolating a thawing fund in lieu f. the refrigerant, and when loose, the side is lifted out and out up into con-sident also.

fruit and vegetable shipping polats for cooling the cars after loading. These plants in the main consist of apparatus for cooling air in large volumes, and this corround air in marge venumes, and this cold air is conducted by air mains to the various cars to be cooled.

Another new field in which refrigeration

Another new field in which refrigeration is extensively used is the drying of air for blast furnaces. Fig. 7 shows one of the latest forms of cooling towers for this purpose. It consists of a concrete tank on which is erected several concer-tric metal shells. The air to be cooled en trie metal shells. The air to be cooled a ters at the base of the outer shell and ascends to the top through a heavy spray of cold water. The air then goes down through an annular passage to the bottom of the inner shell and ascends through a wer of cold brine and is then draws off through the central pipe to the blowing In the tank are located refriger ating colls for cooling the brine which aling cons for cooling the firms which is pumped to the top of the lower and med over and over again. As the brine becomes diluted in time by the water apor condensed out of the air being treat ed, it must be drawn off from time to time and concentrated by boiling. In this direct contact method there is no accumulation of frost in any part of the machine and the cooling is much more rapid than with refrigerated surfaces. For these reaployed for cooling large volumes of air.

#### The Newspaper of the Future By Robert Donald

If I were to attempt to forecast the future, and prophesy whal newspapers of twenty or more years hence are likely to be, I would say with some confidence that daily newspapers will be fewer, the that daily newspapers will be fewer, the tendency toward combinations will in-crease, and colossal circulations will con-tinue to grow. A paper which has not at least a half-million readers will not be considered seriously as an organ of the people. The weak newspapers which can ot spend huge sums on news, on features squeezed out, and the paper run as a luxury or for a mission, and not as a business enterprise, will become too expensive except for millionaire idealists. There will, therefore, be fewer newspapers, but the total circulation will be greater. The power of these national journalistic dread noughts in molding and influencing public tion their luftuence is exercised. Besides the national newspapers, giving an epi tome of life, and presenting the human picturesque side of news collected from all parts of the kingdom and all end of the earth, there will be localized newsthe national press in presenting news. There will, I hope, be a revival of the purely local country newspapers, much improved in form and style, otherwise public life will suffer a serious loss. The pace will they give to sectional interests and we shall have specialized daily new papers to take the place of the specialize

weeklies which now exist. The national newspapers will not con tain iess reading matter, but the pages will be smaller. They will be printe ter and neatly stitched, and will, of course, include pictures in color. The future methods of distribution will be onicker, and circulations will cover gre er areas Airships and aeroplanes will be used for the most distant centers; elec tric trains and metorplanes, running in special tracks, will also be used. In all the chief centers of population papers will be distributed by electric or pneumatic papers will be merged, and editions will

come out almost every hour, day and night.

News will be collected by wireless telephones, and the reporter will always ave a portable telephone with him, with which he can communicate with his paper which he can communicate with his paper without the trouble of going to a tele-phone office, or writing out a message, At the other and the wireless richesphone message will be delivered to the sift-editor printed in column form.

The chief composition to the metastal

#### Why build your factory roof more than two inches thick?

Concrete roofs are admittedly the highest grade of fireproof roofs. Their great weight and resulting high cost have been the only objections urged against them. Were it not for these two factors the concrete roof would be now—as it is destined to be in the future

With Self Sentering you can build a strong, light, concrete roof two inches thick. You can build it without form work or centre of my kind. You can easily and sounceinsally build one of the control of

monator—as were as nat room.

Self Sentering is a new form of expanded in for concrete resaltorcing and general freproofing, is a combined reinforcing and centering—a one-p steel lath and stud.

Self Sentoring comes in sheets 20° wide and up to 12' long. It can be curved in the factory to any desired radius. It is adaptable for practically all classes of concrete construction.

#### India Paper and Its Uses By Willard F. Smith

O NE of the oldest and best papers made is that called india paper, and yet it is little known except to a very few. The formula for making it and the process by which it was made were for many years a secret known only to one mill, and all efforts to produce a similar paper in other mills were failures. However, patient endeavor was at hast rewarded Now good india paper is to be had from at least two different mills in England, one in Italy and one in the United Nataes, and it is interesting to note that the American mill to solve the india paper problem in 1012 was the first mill in the United Nataes to make wood pulp paper, which it did in the year 1854

The essential requisites of india paper are opacity, light weight, low but, smooth fulsa, strength, and a certain rattle cuited "timiness." To embody all these characteristics simultaneously is one of the most difficult tasks in paper manufactures.

Openfy: Is the first thing users of indiapaper took for if the prelating shows through, the paper is of no use. Even with the most copue sheet in light weight, with the most care its required on the part of the printer. His make-ready must be perfect; every line and horder must be inregister with the opposite adds of the page. The utnost care must be excreteed in printing. A day link is sure to give the best results. This does not mean that the average first-class printing establishment cannot do the work; for it can it simply means that care must be given in making ready. The writer was recently informed of a printing job, in which sixteen hundred impressions per minute werrun with great success, proving that production is not restricted by the use of lightweight pages.

India paper must be kept for several days by the printer in a room where the temperature and humidity are approximately. If not quite, the same as in the printing room, and, better yet, if kept in the actual room where it is to be printed. This will overcome curling or "cockle," as it is known to the trade.

it is snown to the trade.

Artention must next be given to the grain of the sheet, which is in the same direction as the length of the paper, while being made on the paper whether. The fibers when run on the machine in many times their summer water certain and resident water certain some circumstant and residenteed has more strength and residenteed has the other more satily than they will break. It is this characteristic which first makes a smooth this characteristic which first makes a mooth fat book. The results when he sheet is printed "with the grain" the other way is to draw it into wrinkles as does a lines sheet when yet through a wringer.

sheet when put through a wringer.
The use of india paper until within a
few years was limited almost exclusively
to Ribbes, prayer books and hymnels. Of

## Complete Electrical Librarv

By T O'CONOR SLOANE, A M., E. M., Ph. D. 5 volumes, 5 14 x 7 15 inches, eloth. Prigs. \$5.00.

An inexpensive labrary of practical and instruct lectricity, for the student, the amateur, the wi-lectrical enganeer, schools and colleges. The title be volumes when sold superative are as follows:

the vidence when add encantally are a follows:

Arithmetic of Electricity, 16 (2) page. 31 (0)

Electricity Simplified, 174 pages, 32 (destrations Electricity Simplified, 174 pages, 32 (destrations Electricity Simplified, 174 pages, 32 (destrations), 160 pages. 160 pages, 16

Special Offer—We will send, by mail or sugress, srepaid to any address in the welld, the above five volumes handsomethered in blue death with silver between, and emboard in a sea folding bast, at the special reduced price of \$5.00 for the set. The regular price of the five volumes, seld separately, as \$7.00 years are \$2.00 by ordering that complete out of use time.

### Telephone Construction. Installation, Wiring, Operation and Maintenance

By W. H. RADCLIFFE, E. E. and H. C. CUSHINI JR., E. E. 4½ x 7 inches, cloth, 171 pages, 125 illustrates. Price, 31.00.

## Practical Steam and Hot Water Heating and Ventilation

By ALFRED G. KING 636 x 916 inches, 402 pages, 304 illustrations Price, \$3.00. ¶ An original and enhaustive work describing all the p systems of means, hot-wester, recover, suppressed vaccinations and the processing to the state of the careadatons, including clusters on the incidence of the careadatons, including clusters on the manifestation of the careadatons, including clusters or features are methods of the fine of the careadatons, cost and such other tits incommotion as unates it as infedermentable with for health intermentation as unates it as infedermentable with for health and the careadatons, the careadatons are considered to the careadatons.

## Modern Steam Engineering in Theory and Practice

By GARDNER D. HISCOX, M E. 61/2 x 91/4 inches, cloth, 467 pages, 405 illustrations. Price, \$3.00. A complete and practical work for stationary enga-ramen dealing with the care and management of bodies supp., superheated steam, refrigorating machinery, formers deaking with the care and management; pumps, superheasted steam, retrigenating med motors, derators, air comprements, and all on which the modern sequence meet be familiar, and Blustiates the proportion and use of steam? of postage in the various types of control in our highly proposed to the proposed of the

One progressive advertiser changed from the heavy catalogue paper used many years in his annual cate paper used many years in use annual cata-logue to an inexpensive form of india pa-per and saved over \$20,000 on the issue, the principal item being seven cents in postage for each catalogue. A good illustration of the saving in bulk and weigh over the paper heretofore used is found in the new edition of Webster's dictionary. The old dictionary measures 8% inches by 11% inches, has 1,766 pages, and weight 0 counds 1. and weighs 9 pounds 11 ounces. The new edition, printed on india paper, is size 9 by 12, has 2,624 pages and weighs 6 pounds 13 ounces. The old edition is four inches thick and the new edition two and a quarter inches thick. From this it is seen that a book with pages of approximately the same size, the number of pages has been increased about 850, the thickness reduced one and three fourth inches and the weight reduced nearly three

> In addition to the advantage of small bulk and light weight, both of which are so important, india paper has a wonderfully soft amouth surface. It takes line cuts, steel engravings and zinc etcl perfectly and very good half-tones. has one more quality which is really re-markable, and that is it does not suffer from rough usage as one might think; it stands up under hard wear, and if badly crumpled by any mischance it can be smoothed with a heated iron and made as good as new.

# A New Mail Carrying Railway

(Concluded from page 252.) being transmitted without physical con-tacts through pilot coils imbedded in the track member leading to the operator's

When descending a grade, power is re-enerated back into the line, the conserved serving better than a physical brake in keeping the cars close to syn

This system has certain advantages over niniature electric railways without mo tormen, which must be perfectly obvious The same unit of power will se farther and faster when applied as a direct push or pull than when exerted in directly through gearings, bearings, axles and wheels in the form of wheel traction. In lieu of the motor, its accessories and housing, the cars carry only a light pro-pelling member, which being placed beneath the car leaves the entire car space free for freight, thus effecting a saving in weight, care and cost, and increasing the carrying capacity. Instead of being limited to moderate grades, the cars may be designed to take any grade, enabling the delivery and dispatch of mails from ter minals located in second story distributing rooms of post of ces, as in the New York Central terminal station, thus obviating the cost, delay and inconvenience of re handling, as well as the lifting and lower

ing by elevators.

As each wheel turns independently of grinding on grades, caused by the rigidly connected wheels of wheel traction sys-tems, is eliminated. The speed of the cars, not being dependent upon the tractive of fort or revolutions of necessarily small wheels, is limited only by mechanical laws and strength of construction. Instead of the irregular and disconnected behavior of motor-driven ears, which render oper tion under close headway hazardous, all tion under close headway hazardous, all cars moving in synchronism, like buckets on a belt, must move uniformly over suc-cessive sections of track, thus rendering the system immune from collisions while and owing it with a far greater carrying capacity than can be expected of systems which require block systems and minutes which require block systems and minutes of headway between cars. Cleanly, a sys-tem which allows the dispatch of cars every five seconds has twelve times the capacity of systems which require at least sixty seconds between cars.

The Editor is always gird to receive for examination illustrated articles on subsects of timely interest. If the photographs are somity, the articles short, and the facts authorite the contributions will receive special alterition. Accepted articles will be paid for at regular space rates.

The purpose of this fournal is to record accurately, simply, and interestingly, the world's progress in sointific knowledge and industrial achievement.

#### A Destroyer of Destroyers

The close of the Russo-Japanese War, the childr engineer of a Russian torpetholiout descripter, who had passed dirough twelve monliss of neithe service in the defense of Port Arthin, children at this office, and in discussing the expectence of the Russian destroyer feet during the sloge, stated his helief that the larger and faster destroyers of the future would become so swift, able and powerful, as to call for the design of some special type of vessel to deal with them

That convention is called to the writer's mind by a dispatch from one of the British dockyards, describing a new type of cruber which has been dockmated by the First Lord of the Admiralty as a "destroyer of doctropers". The vessel is described as being of 3,500 tons displacement and capable of a continuous sen speed of thirty knots. She is credified with a belt of five-lined armon and a battery of 47- or 6-linel rapid-fire gams It is stated that eight of those ships are at present under construction for the British many.

If the vessels are being built for this specified day, their speed, hittery, and protective quality are most too large for the day assigned to them. The modern destroyer has graduated from the "bart" into the "ship". That it is embourts searcothy was proved in the wastern of the state of that vert, when our destroyer feet, on its way to claim, was subjected for several days to one of the forcest storms ever experienced in the western North Matafite and these vessels, but fremembered, were of much lighter construction than those which are now being built for our many

The latest destrovers, moreover, are equable of being driven at full speed under unhellevenlik severe conditions and any vessel which is designed for the special work of overtaking and slinking such vessels must here sell be a large, fast and very stanneh ship. Moreover, it is perfectly logical that the destrover of destroyers hould be an irramoral vessel; otherwise she would be at the metre of the quite formidable arranment which is now mounted on the destroyers. The one, three, and sky-pounders of the data of Devey and Sumpson have glove pixer to high-vedently, longraings, impld frees of four-back cullber, and the ship that undertakes to four down a quanty armed with such pleces as this must needs earry protective armer of high spunity and reasonable thickness.

#### The Interstate Commerce Commission and Safety on Railroads

MILL is to be latireduced in Courcess girling the Interestant Commerce Commission fail paper to operating condition to the readingly equipment and actual operating conditions of the ratherests of the Patient States so far as they are related to the safety of the travellog public. The full is based upon the suggestions of the officials of the Commission. Its object will be to compete the ratherests to maintain that readyment and routheds at a sufficient standard of excellence, and for run their traings only at mach speeds as are justified by the existing physical condition of the track, equipment, and simula system.

As matters now stand, the Commission is empowered to investigate all ratifords weeks and make such suggestions for the improvement of the tracks and estipment and the methods of operation as it may deem necessary. Beyond this the Commission cannot go; its recumentations are not obligatory upon the ratiforads it courseds that the ratiforads have ignored its findings, it contends that the ratiforads have ignored its findings in the interest presenting the traveling public, it finds itself in practically the same predictment with which it was controuted in the matter of rate making, before it obtained adequate Federal authority to enforce its ratification.

Now it is certain that it bill which seeks to confer input the Commbision such far-reaching powers as this will be met with the strongest opposition, multip on the ground that it places in the hands of a few men the power to impose upon the railronds expenditures for roadbed and equipment which might prove to be interesting the provided of the provided provided in interesting the provided in the provided provided in the interest provided and explain the provided provided in the interest provided in the provided provided provided in the provided p

The Importance of the bill and the grave consequences which would follow from a too soulous exercise of the powers which it will confer, are not be dealed, as will be sew-from the fact that if the Commission, exceeding its enlarsed power to the full extent, should order the rallwoods at once to replace all woods and several power to the full extent, which is not the property of the property of the power o

The fundamental principle of the Interstute Commerce Act of ISSN vas that facts, regulations and practices affecting interestate transportation should be reasonable and just and devoid of an unduc and unreasonable discrimination. Subsequent legislation strongthoned the hands of the Commission by giving it the power to cuforce its suggestrous and impose possibles in 1903, during a concressional investigation into the relations of curriers to the coul and oil badness, an act was passed increasing the power of the Commission to regular interstate consucree and conferring upon it authority to prescribe for the future just and reasonable rates, regulations and practices. During the period from 1887 to 1906 there were fitted with the Commission 188 claims, and between the passage of the Hepsium Act of 1906 and the year 1911, \$135 compilities were field, and 2,900 declatons were rendered.

We commend to our residers an article written by Judge Judge of Clements, then chairman of the Interestate Commerce Commission, which impeared in the SCHATTHE AMERICAN OF JUDGE 1891. The facts takes given are taken from that article, in which the Judge went on to say that, up to that time, 220 crimal prosecutions had been indituded for violations of the act, and about three quarters of a million dollars in these had been collected from guilty shippers and carriers. Reparations, aggregating over \$2,004,000, had been ordered in format converted cases, and over one million dollars had been allowed upon the application of carriers on submitted for an analysis of carriers on submitted for an an admitable impaires

The passage of the Intertatie Commerce Act of 1887 was streament) redsted upon many grounds, constitutional and otherwise "It was aliceed," says Judge Clements, "to be radical, revolutionary, un-American and or ningdatable interference with the freedom of contract and with nucleut commercial usages." Nevertheless, we doubt if to-day anyone, either Inside or outside of rullroad circles, will deay that the work of the hierotatic Commerce Commission has been of Inselfan bide beautiful his to the rullroads and the public at large.

It is scarcely necessary to state that the movement of strengthen the hands of the Commission for strengthen the hands of the Commission for strengthen the hands of the Commission fallows the so or three veers with the New Haven Rallowan to its catesaw to secure certain physical changes in the instances of the condition of the condition and equipment which, in the quintin of the Commission, were necessary to neveral such first seekens as have under that read notorious. It is recent understand and, indeed, the Commission in its recent report has made it elever, that if the relition decompany had made certain hapro-emeants, both in the malaronized and operation of list rands, some of the later accidents, in all probability, would not have occurred. The Commission suggested these changes to the company, and their its power cessed. It lacked the Federal and the Commission underset is industry as a matter now stand the Commission that it is power crossed. It lacked the Federal and the Commission will be able to investigate, draw fits conclusions and enforce its mandates.

The excellent record of the Commission in its hand-

ling of the rate situation is an answar to the objection which is sure to be raised, that the peacege of the bill may sudject the railroads to the imposition of obligations in the way of wholesale betweeness and improvements which will be ruinous to their prosperity. There is nothing to justify such a fear. Federal control of the physical equipment of railroads, so far as it has been exercised in the past, has been marked by forbearisme and just discrimination. This was shown in the matter of the enforced equipment of trains with altrinkes and automatic couplers. Whenever a railroad proved to the Commission that its financial condition was such that it required more time for carrying out the Commission's mandate, the time was allowed; and we have every reason to believe that the same spirit of fairness will govern the Commission in the matter of roadbed and rolling stock and the proper adjustment thereto of the speed of trains.

#### Bomb-dropping in the Balkans

T is even yet too early to give a detailed or critical account of the part that bomb-dropping played in the war against Turkey. Enough, however, has been learned from the reliable discussions which have appeared in the technical press to confirm the conclusions reached lone again by military men

sluns reached long ago by military men.
The question of bomb-dropping must be viewed from
two aspects. What is the effect of the dropped bomb?
Can the bomb-dropping avlator fly sufficiently high to
escape an ouemy's bullets and still drop explosives accurately?

Experience in the Baikan campaign seems to show that the moral effect of an exploding bomb that falls from the sky is greater than its natural destructive effect; also that a height of at least 4,000 feet must be maintained if the bemb-dropper is to perform his task in safety.

Thus un December 15th, 1912, Montonests, on a flight from Trevers to Janins, three bombs from a height of from Trevers to Janins, three bombs from a height of 5,000 feet and created a panic; but the fabric of his wings was panicared by boulter builters, on that he made-his seeape not without difficulty. Another Greek, Capt. Barres, was reacted by builters even at a height of 6,000 feet, but he too made good his seeape. On December 22nd, 1912, Moutonesds three builts from a height of 0,200 feet at Janina with good effect; just again his machine was hit is builters, without teleng crippled. If machines can be struck at such heights, the aviator escapes only by the luckteet chance.

A responsible witness, the English filer Hodley, who was with the Bulgarfans before Adrianophs, testifies that one of the many minurets of a mosque was destroyed by an acceptance bomb dropped from his machine. This speaks well for the destructive power of the light bombs curried by aeroplanes. On the other hand, the hit was a strike or luck. It was not even not, the hit was a strike or luck. It was not even nothing the property of the control of the property of the control of the property of the property

If the Balkan experiences teach anything, they teach the impurionce of aeropiane bombs lies in their mansl effect—in the impression created that the machine in the sky is a real source of danger. It is conceivable that in a kind of hand-to-hand fight (the machine buxefug the ground and depending on speed for its safety) bombs might become very formidable. But at great heights the machine gun is superior to the bomb.

There are several obvious reasons for this superiority of the yan over the bumb. It is clear that if a bomb is to be drouped accurately, the pilot must fly almost directly over the target and exposs blueself to the long point-blank range of high angle infantry fire. If the marksomen are good lie may be brought down. But if a machine gun is mounted in the servolance and the variator relies upon it instead of upon bombs, he may keep well to one side of his target. Circling around how lill quickly get the range. Wher is snown, he has all the advantage of noting the effect of his bullets from a great elevation, as advuntage much covered by artillerists and infantry officers who experience the greatest difficulty in sevening exactly where their ministes strike.

That the day is not very far distant when machine guns will be mounted on seroplanes was clearly indicated at the recent Parls and London expositions. On both of these occasions very large hiplanes were exhibited with machine guns mounted in very advantageous positions. The wespons were carried in the foremost part of the hiplane in the nose of the pointed car, so that they could cover the entire field in front of them. In that position, however, they could not be used at all against an aerial pursues.

Apart from the greater accuracy which can probably be attained with machine gun fire, bouths my become a source of danger to the machine in which they are carried. If the fire of an infantry regiment or two be concentrated on an eroplane there is a chance that the explosive freight may be struck, with disastrous requist. There seems to have been some inkling of this danger in the Balkans, for French pilots before Adrianople refused to take bonds absorts.

MAKEN SERVE BEAUTION

Essevisight Projection.—Some suggestive experiments have been made on German warships with lighted projecties, which it is thought may take the place of the electric searchlight. The projection, which is filled with calcium earbide, is fixed from a canson, and since it is lighter than water, after striking, it comes to the surface. During its immersion, water is automatically admitted, and produces acceptione gas, which burns with an itumination equal to that of three thousand candles. The placing of a few of these around, a distant enemy would certainly put him at very serious disadvantage.

The Assouan Dam on the Nile can be called upon to The assessant loss as the true can be esticed upon to furnish a large amount of hydraulle power for operating an electric plant; it is estimated that it would furnish no less than 150,000 horse-power. During five months in the autumn and winter the water of the Nile no-cumulates in the dam, and when it overflows the height of the resulting fall and the great volume of water would. furnish some 150,000 horse-power. Current could be used for the manufacture from the atmosphere of nitrogenous products for use as fertiliser. This would be of great value to the country, for it is stated that Egypt imported no iess than \$3,500,000 worth of fertilisers

The First Passage of the Panama Lock.—On September 20th the first passage of the looks at Gatun, Panama Canal, was made by a sugboat. The water in Gatun Lake was 65 feet above see level, or 20 feet below its ultimate level. The upper look was filled above in the forenoon, and in the Abertsoon the water was admitted. forencon, and in the afternoon the water was admitted to the middle and lower looks. At 4445 P. M. the level in the lower looks having reached the level of the Atlantic, the gates were swring open and the tug entered, the historic event being heralded by the observe of the assemblet thousands. At 1645 P. M. the tup passed from the upper look to Gatun Lake. The test was made slowly and with complete success.

Twelve Years Experience with Automatic Stops.— The automatic stop has had some twelve years of trial under various conditions, with the result that four municipal rapid transit systems have them in auti-factory operation, and three of these, after demonstrat-ing that the stop increases both the safety of traval and the traffic capacity of their systems, have exand the traffic capacity of their systems, have ex-tended their use. The finest performance is that recorded in the New York city subway, where the stop makes it possible to run trains under a headway of one minute and forty-three seconds. The automatic stop is a teli-tale upon careless or inefficient motormen, since it affords a record of the fact that a signal has been overrun.

Noiseless City Streets .- There is coming into use Noiseess City Streets.—There is coming into use in Germany a chesp and ready method of amphalting a stone-paved street which is showing good results. The spaces between paving blocks are cleaned out to the depth of about an inch, and then a layer of melted asphalt is flowed over the street surface, the depth of the layer being about one inch. Before it is cooled, sand is sprinkled on and the surface is smoothed. At Frankfort a section of this kind is now laid, and it appears to stand the wear remarkably well. Should the method eilent means for deadening the noise of city traffic at a small expense. It is quickly carried out and it need not stop the circulation on narrow streets for any length of time. Moreover, repairs are easily made.

Successful Gaseline Locomotive.—At the Schneide mines in France there are being made trials of a new light locomotive with a 70 horse-power internal combustion engine. A novel feature is the use of naphthaline as fuel, employing a special carbureter. It is claimed that the present locomotive is the best solution of the problem of a small locomotive for use with trains on a narrow-The trials made near Havre gage ranroad. In the trans made hear navve sould excellent results as to general working as well as fuel consumption. Advantages over steam locomotives are: rapid starting, no boller upkeeps, suppression of water supply along the road; ease of driving and absence of danger, reduction of dead weight to the least amount, small bulk of fuel on board and absence of smoke and

The Forty-thousandth Lecometive.-Bhat a firm of builders should have recently completed its forty-thou-sandth locomotive bears testimony to the magnitude of sanda locomotive local testumory to the magnitude or the locomotive-building industry of this country. The Baldwin Locomotive Company, who have accomplished this feat, built their first locomotive in 1892. The one-thousandth was turned out from the works in 1881; and in 1880, the five-thousandth locomotive appeared. and in 1890, the five-thousandth homomotive appeared, to, 10,000 was built in 1892, and No. 20,000 in 1902. It took only five years for the company to build its next 10,000 locometives, and the present year sees the completion of the forty-thousandth, a fast passanger "Pacific" type. This locomotive has cylinders 26 inches in dismeter by 26 inches critics, 80-lank driving wheels, 4,225 square feet of heating surface, weighs 189,500 peptude, and has a treative force of 38,300 pounds. It was built for the Punnsylvania, Railread.

#### Science

Sevey's Generosity.—Ernest Solvay, discoverer of the soda process that bears his name, celebrated the 50th anniversary of his discovery on the 20th ult. by giving more than \$1,000,000 to educational and chartable institutions and to the employees of his firm. The universities of Paris and Nancy each received \$100,000.

The F-Rays Do Not Exist .- The discovery that was announced of a new series of rays, the F-rays has just been contradicted. According to very precise and detailed information published by the Eclair, it appears that the results obtained are not at all conclusive. The F-rays appear to be an illusion similar to that of which the scientific world was a victim when the pnyacust Blondiot, professor at the Faculty of Nancy, professod to have discovered the N-rays. tific world was a victim when the physicist

Fermentation in the Paper Industry.—Among the recent improvements in handling paper making materials is a process for extracting the starch from cotton rage that are used in making linen papers. Practically all cotton cloth has some kind of a filler, and much all outton cloth has some kind of a filler, and much of this is starch. In dispings from new cloth there is a considerable amount of starch filler. It was the practice formerly to soak the rage in warm water, and then to boil them in an alkali solution. But the effect of the alkali on starch is very slow, as it causes the starch to swell up, so that the solution reaches the inner part of the starch grains only with difficulty. Malt is added in the proper amount to convert the starch into a soluble sugar which readily dissolves out of the filter of the cloth and leaves it free of the filler. The active principle of the malt is the "enzymes" that attack the starch just as they do in the brewing process, and convert it into a form of do in the brewing process, and convert it into a form of sugar that is easily disposed of.

Delavan's Comet.—A telegram received at Harvard Observatory from Capt. J. L. Jayne, of the United States Naval Observatory, gives the following position of Delavan's comet as observed by Burton:

Relavan s comet as observed by Burron:
September 27.7204 G.M.T.
R.A. 21h. 50m. 37s.6
Dec. —I deg. 37 min. 33 sec.
The following position received from Prof. W. W.
ampbell, of the Lick Observatory, is from an observation by Prof. Aitken:

September 27.7201 G.M.T. R.A. 21h, 50m, 38e,5

R.A. 21n. 50m. 58a.5 Dec. —1 deg. 37 min. 36 sec. A telegram from Prof. A. O. Leuschner, of Berkeley, alifornia, states that Nicholson and Miss Kidder find elavan's comet identical with Westphal's by inter-Delayan's comet identical with weappung polation applied to the ephemeric given in Astronomiss Nachrichten No. 4619. The period is 61.121 years.

The Death of Professor J. R. Eastman.—Prof. John Robbe Eastman, the astronomer dued at a pravate hospital at Franklin, N. H., on Reptember 20th. He was 77 years old. Prof. Eastman was an assistant at the United States Naval Observatory at Washington from 1961 to 1805, and professor of mathematics since then He was retired for age in July, 1898, with the rank of captain. In June, 1906, he was promoted to the rank of rear admiral. Prof. Eastman was the first president of the Washington Academy of Sciences and was in charge of the mendian ornel work at the observatory from 1874 to 1891. He was also in charge of the trainst of Venus party at Codar Keys, Fla., in 1882. Prof. The Death of Professor J. R. Eastman,-Prof. John from 1874 to 1891). He was also in charge of the trainst of Venus party at Codar Key, Fla., in 1882. Prof. Eastman prepared and edited the Second Washington 80,000 observations made at the Navial Observatory, 1889-91. He was the author of "Trainst Cruef Observa-tions of the Sun, Moon, Planets, and Comets," 1903.

Neujmin's Remarkable Comet.-Neujmin's comet resumms a semarance Comet.—Neugmin's comet has aroused not a little interest among astronomers. It was discovered on September 6th last, five days after Metcall's comet. From prate sources we learn that the period of 25½ years, calculated by Einarson and Nicholson, is probably correct and that the object that the period of 25½ years, calculated by Einarson and Nicoholoson, le probably correct and that the object is really a comet, although a very queer one. It was discovered in the Crimes, where the Pulkowa Observatory maintains a station mainly for the observation of asteroids. The object was found on one of their photographic plates and was at first supposed to be an asteroid, as there was no evidence of nebulously. The discovery of new asteroids is not sabled to America, but the discovery of new comets is no cabled. When notice of the object as an asteroid reached Bergersdorf, near Hamburg, Germany, it was observed visually, and it was decided to be a comet. Then it was that the news first reached America by cable. Viswed in the great telescope of the Yerkes Observatory, the object indeed appears like an asteroid. Bence the object in nearly all nucleus. Were it not for the presence of the lineaughtubes it from an asteroid. Hence the object in hearly all nucleus. Were it not for the presence of the longate funds as the stacklike appearance of the object might easily missed even a practiced astronomer into taking it for an asteroid. The comet is bardy visible in a five-inch telescope as a small faint haze. The exame it is a five-inch telescope as a small faint haze. The exame it is a change on a sure of the named eye.

#### Aeronautica

A French-German Air Treaty. - The Luneville incident has resulted in a convention between France and Ger-many, which provides for the future landings of aircraft in the respective territories of the two countries In case military aircraft in distress are driven over the territory of the neighboring country, the pilots are to hoist appropriate signals and to descend as soon as

Harnessing the Flying Machine. Thomas William Carey, of New Orleans, La., has secured a patent, No. 1,070,011, for an aviation apparatus which includes a circular trackway with upper and lower tracks and a flying machine held to the trackway and guyed to pre-vent irregular movements. Some of the guys extend fore and aft to prevent pitching and others extend trans versely to prevent canting or rolling.

Airship Starting Reservoir Acts as a Float .- A patent, No. 1,070,576, has been issued to F. B. Bell, of El Paso, Texas, for a flying machine in which the gas engine is started by air from a reservoir for compressed air and the ervoir is located in the lower part of the machine so it can serve as a pontoon when the machine descends upon water. A series of tanks form the reservoir, and an air compressor driven by the engine compresses

Moreau Wins the Bonnet Prize .- On September 24th, Moreau with his self-raping scroplans won the Bonnet prize by flying half as hour without touching the levers. Lieut. Lafon accompanied him as a passenger to verify the performance. It is said that a strong wind was blowing at the time, that the monoplane rolled and pitched, but invariably returned automatically on a level keel. The SCIENTIFIC AMERICAN has fully de-scribed and illustrated the Moreau machine

The New German Zeppelln "L.H."—The Zeppelln works have completed the "L.H." Sho us and to be a far after type than the ill-fated "L.I." Her exact is 641 feet; in other words, also is 10 feet lower than the "L.I." Her breathth is 40 feet. There are three cases, two of which contant the ungrane, while the third is intended for the officer in charge. The total engane is 400 feet. The New German Zeppella "L.H."-The Zeppelin is intended for the officer in charge. The total engine power delivered by the four motors of the ship is 800 horse-power. It is hoped to attain a speed of no less than 75 miles an hour with this vessel.

A Wind Deflector for Wings .-- M. Constantin, a well known designer abroad, has applied the princip of the "saute yent" or wind deflector to the wings an aeroplane, and it is said that surprising results have been obtained. The deflector comprises places forward of the wing and curving upward toward the rear in such a manner that the wind is deflected up and away from the wing. Thus the wings of the aeroplane are protected from the direct force of the wind on their upper surfaces. The object of the device is to increase the rarefaction of air above the wing, thereby increasing

A New Airship Type.—The airship "Veeh I," which made its first ascent on July 8th, last, at Düsseldorf, embodies some new principles in its construction. The attempt has been made to combine the merits of rigid and non-rigid systems. A steel tube framing covered with fabric runs from the bow to the stern beneath the gas bag and is of such proportions that it contains the cabin and serves as a passageway. This keel frame, for such it is, houses two 130 horse-power Merwedes motors, the pilot's cabin and the passengers' cabin. The vessel is driven by four wooden propellers carried on outragers. A large vertical rudder and a horizontal rudder are mounted at the storn. The cutre level frame can be very quickly detached from the curvelop gas bag and is of such proportions that it contains and separately transported. The vessel is 80 meters long, 30 meters in diameter and has a capacity of 8,000 meters of gas.

The Gordon Bennett Race.—The race for the Gordon Bennett trophy was won this year by Maurice Prevent. Because there was only one foreign competitor, a Belgian named Crombez, the race was really a contest among Frenchmen, and hence aroused but little interest. For all that it was a remarkable competition, chiefly beuse of the record-breaking speeds attained. Maurice evest covered the course of 124 77 nules in 59 minutes 45<sup>§</sup> seconds. His average speed was more than 125 miles an hour which is more than two miles a min-That is the fastest speed yet attained in a flying machine. There were two other French competitors besides Prevost, namely, Engene Gilbert and Emile beauses Prevost, namely, Jugues unitert and Emite Vedrines, also broke all speed records, but he finished nevertheless 1 minute 54 seconds behund Prevost. Crombez, the Belgian, finished last, his time being 1 hour 9 minutes and 52 seconds. There was not much variety in machines. Prevost, Cilber and Crombez flew Deperdussins, and Vedrines a Ponnier Prevost. Oilbort Prevost cut down the surface of his wings until they revose out down the surrace or his wings until they were only 96 feet square. There can be no doubt that this helped him to make speed, but it also made landing dangerous. He flew at midday and kept rather low, rarely exceeding an elevation of 35 feet.

# The Biggest Flying Machine in the World

The Remarkable Biplane of Sikorsky

SCIENTIFIC AMER was called to the gignotie biplane which was designed by Sjkor sky and which flew for just over on hour with seven passengers at St Petersburg

According to a detailed descrip tion published in the Zeitschrift fur M o to t luftschiffahrt, Sjkorsky's machine follows the general lines biplane of 11 Farman Sjkorsky's is the biggest flying machine that structed and flown. It has a span of 28 meters (91.86 feet), and a length of 20

meters (05.6 feet). The supporting surfaces have an area of 120 square meters (143.52 square yards) The lower plane has a span of about 51/2 meters (18.04 feet) less than the upper plane

The machine is driven by four motors of 100 horse-power each, mounted on the lower plane Each motor drives directly a propeller of 2.6 meters (85 feet) diam-The propellers are tractor rotating in front of the supporting sur faces and the motors, so that a cooling blast of air is directed against the motors and radiators

The starting and alighting gear is very stoutly built. There are four landing skids-two long ones in the middle beneath the boat body, and a short one on uch side beneath the lower plane. wheels on which the machine is carried hetween the skids on each side. The wheels are provided with very heavy pneutires inasmuch as the s over 2,700 kilogrammes the m tionnds) unloaded and about 3,200 kHz. grammes (7,054 pounds) with passengers, fuel, etc. The axles of the two pairs of wheels are secured to short skids which are provided with two brackets to the preper ends of which two rubber straps are fastened, thus providing an elastic con-nection with the main skids. The short skids are connected on either side by cables with the wheels, and the wheels in turn are fastened by rubber straps to the skids so that they may yield laterity. The tail consists of a single surface and

elevator combined, above which two verti-cal rudders are arranged. The supporting surfaces are provided with flaps or In addition two vertical surfaces,

one on each side, are mounted below the upper surfaces about six meters (1968 feet) from the central axis These surfaces measure about 1.6 meters (5.24 feet) square

The pilots and passengers are comfortably housed in a calin, so that they are well protected from the wind and weather. The lower part and the floor of the cabin are covered with sheet steel, as well as the front portion of the boat body Celluloid windows are provided. The seats are arranged di three rows behind one another. The two

This huge flying machine recently flew for just over an hour with seven passengers.

front seats, between which is a sageway, are occupied by the In front of each pilot is wheel to operate the elevating rudder and ailerons respectively, and a foot lever to control the

vertical rudders Each motor drives a tacho-meter through the medium of a flexible shaft. The four tachoeters are mounted in front of

ficult to keep all four motors run ning at the same speed, Sjkorsky intends to use a connecting shaft, which will be thrown into engagement with the motor shafts by means of beveled gears. By means of clutches a po

es a pair of motors can be thrown in or out; for example, the two outer mo-tors or the two inner motors.

tated in Front and two bear found, however that by arranging the propellers in a row perpendicu-lar to the line of flight, greater efficiency was obthe motors are thus more readily cooled. It is said, however, that the motors will be motors will be brought nearer the boat body and between each pair a c c ommodations are to be provided who can watch them during

In the after portion of the

cabin, a wireless telegraph transmitter and receiver have been installed. The antenne extend over the main supporting surface and back to the tail.

The cablu is so spacious that several persons can easily be accommodated. It is even possible to manipu-late a machine gun and two acetylene searchlights. The speed of this gigantic flying muchine is about 90

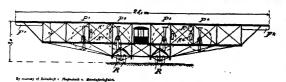

The speed of this grantic nying michine is about 90 kilometers (56 miles) an hour. Nearly every Russian record has been beaten by this machine as well as the world's record for seven passengers. On August 1st tho machine few with seven passengers for over an hour. With twelve passengers the machine has flown

for more than 15 minutes. The Russian ministry of war has bought Sikorsky's biplane and intends to build more like it. While the machine has flown very suc-cessfully, some difficulty has been experienced in launching and alighting; for a enced in launching and slighting; for a large open space is required to start and land. Indeed, the machine must cover about 200 meters (605 feet) before it can get into the sir. Moreover, the prelimin-ary run must be made on very firm ground. In sand and plowed land the wheels sink too deep. Because of these difficulties the running gear has been changed. Four wheels are now mounted on either side in pairs behind each other, so that the machine has in its present so that the machine has in its present form eight wheels. The supporting sur-

form eight wheels. The supporting sur-faces are made in parts so that the entire machine may be more readily stored. The biplane is built chiefy of steel tubing and wood. The supporting surfaces are covered with cotton fabric impregnated with a special compound. The rear portion of the fussinger is also covered with impregnated fabric. Because of the great weight of the flying machine a slight shifting of the load (130 pounds) does not disturb the equilibrium. cently the passengers have a certain amount of

Sikorsky, the designer of this remarkable craft, is said to be only 23 years of age. His interest in aeronau-

tics was aroused when the aeropiane made its first suc-cess in 1996. He started in by designing a headless biplane, and followed this machine up with other aeroplanes of both the monoplane and biplane types. Eventually be went to types. Eventually be went to France where he made a thor-ough study of French aero-plane practice. Beturning to Russia he began building maagain on his own acmall military machine which low exceedingly well

# Constructing a Building Upside Down

A Seven-story Building Suspended Over a Twelve-story Structure

N EW YORK may boast of some astonishing achievemants in structural engineering, but few are more extraordinary than the hanging building of the Coasolidated Gas Company. This is a 7-story structure suspended between two 19-story buildings over one of 25 stories that was not originally designed to take any additional load upon its own columns. The circumstances that led to this odd piece of engineeting are interesting. For many years the company had owned an old building on the corner of Fiffeenth Street and Irring Place. It had how outgrown the

The decrumstances that led to this odd piece of entineering are interesting. For many years the company had owned an old building on the cerner of Fifteenth Street and Irving Flace. It had long outgrown the building, and various departments had been housed in neighboring offices. It was decided a few years ago to tear down the old arrecture and build a more commedican one. In order not to disturb the office work during the construction of the new building, the old building was not torn down until after a new 12-story building had been exceted on a lot immediately to the east of it. The 12-story building was receded in record time by the engineers of the company. Work started in November, 1910, and in alx months' time it was ready for occupancy, after which the old building was torn down. Before work had commenced on the old site more property had been acquired to the east of the new

Before work had commenced on the old site more property had been acquired to the east of the more building, and sales to the south of the old building on Irving Place. It was then considered advisable to here all the gas companies of the consolidation in one central building, but this would require more floor space than could be afforded by a 12-story structure over the

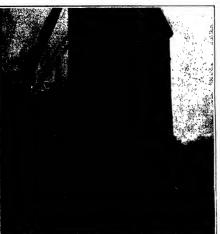

than could be anorated by a 12-story struc-entire property. Accordingly it was planned to carry the building up to 19 stories. But in the middle of the property was this new 12-story building, whose columns had not been designed to support any additional stories. To be sure the columns of the building could be strengthened, but this would necessitate ripping away the walls built about them, which would seriously interfere with, if it did not actually interrupt the work in the offices. It would be possible to bridge across the building with heavy girders and carry the structure from there up; but these girders would have to be 8 feet deep, which would mean that the rooms on that floor must necessarily take the form of hallways be-tween the girders with small windows ar the ceiling. Furthermore, the appearance from the outside would be architecturally bad; the break in the design could not very well be concented. According to was finally decided to carry the br ross at the very top of the structure and om at the very stories from it, the col-pend the seven stories from it, the col-pend of the new 10-story building on each being made doubly strong to sup-t the additional load. This called for form of construction that was per d from the top down

strended from the top cown. Engineers are accuratement to ment the unsupercied, and while this problem was unique, it presented no very certous difficulties. The exterior of the building was shelping if it if it. It. Hardenburg, but the manufacility is not in the contraction of the building was shelping if it is in a planning and

is now being carried out by the gas company's own staff

—Mr W Culien Morris, engineer of construction, assisted by Mr A W Stark and Mr. II W Airich

In order that no break might appear in the architectural design where the new building joined the now "old" 12-story building, it was necessary to expose the columns at each side of the old building, and bring the new 13-story columns in contact with the old ones. Thus the pillars at the junction of the old and the new suildings would not be any white than the older billars.

The axis sharily columns were exected to support the girders staming the old building and to carry their share of the new construction. The girders are stranged in pairs at the construction. The girders are stranged in pairs at the construction of the building, where the span is 62 feet. There was not these bong stricters are such at the reast, where there is a well in the building, the span is only 42 feet, and here shape girders are used. The first pair of girders is supported on a based level than the rest. The front columns are cusped with the first the columns are comped with their These are further supported by the property of the property

when are supported it story angure are uniques, beavy wing plates reliable with gausst plates. The larger gladers weigh 40 tons, and are 8 feet deep. There is almost 1½ square feet of metal in their cross-sectional area. They were lifted to the ton of the building by a large deer(the of 88-ton capacity. The enormous boun of this dictrick, 72 feet long, any

he seen in one of the photographs. It took 23 minutes to holst a girder from the street 250 feet to the top of the building

The accompanying drawing shows the method of attaching the hangers to the gliders. A pair of girders may be seen at .t 4, both broken away so as to show the construction Between the girders is a dhighragm B, and riveted to this on each slde, back to buck, are two channel from ('C', which constitute the hanger. Two butt plates D serve to secure the filler plates E to the channels and the disphragm. In one of the photographs the first hanger may be seen suspended from a girder. will be observed that the cover plate of the hanger is cui nway at intervals in order to lighten the hanger. Unlike the sary columns the hangers are under tension instead of compression, and they do not need a cover plate to prevent them from buckling The structure is now near ing completion The stonework has been ing completion. The stonework has been carried up the face of the building, and there is nothing to show where the new joins the old. None of the weight of the new structure is curried by the old building, except at the rear, where formerly a large water tunk was installed. To support this water tank the columns here were made doubly strong, and this extra strength was utilized to carry some of the weight of the new structure

One of the photographs shows the lugenious method employed for transporting fuel to the boiler plant.

# Night Attacks in Modern Warfare

#### Shells That Illuminate the Enemy

By Major H. Bannerman-Phillips

A MONG the many nerve-trying developments of the art of war in recent times, night operations are likely to assume great prominence for various excellent To steal a march on an enemy and out maneuver him; to avoid the unwelcome observation of his aerial scouts, planing at lofty altitudes, securely immune from the fire of terrestrial marksmen; to tra-verse ground which offers no cover from the view and fire of the enemy in daylight; to carry on an attack commenced before dark and convert it into a successful fight to a finish during the intervening period before the following dawn reveals one's dispositions, and, more important than all, to take the enemy by surprise, and thus enhance the chances of success ten-fold able to act by night rather than by day, although nocturnal operations are by no means so simple as those carried on in daylight and should only be

attempted by selected and senwho have had special and extended training for the express purpose in peace time They involve a thorough recon-naissance of the ground even in the case of an ordinary night march, and to commit troops to a march or an assault on an enemy's position by night without such a on is to risk playing into the hands of the enemy. In the case of a march by night the route ought to be carefully gone over by the reconnoitering officers both by day and night, compass directions taken and landmarks noted, and unless one has actually carried out such r preliminary double recommissance and taken part in the subsequent operations it is difficult to appreciate how much de-pends on the care with which this duty is performed. In the case of an advance s country with a view to uttack by surprise it is remarkable how obstacles which can be avoided or negotiated with ease in daylight may become veritable pitfalls by night, bringing confusion as advancing troops and possibly which may revent their presence and cause the failure of the whole operation.

In all cases secrecy as to previous intentions and concealment of the operation itself are of the utmost importance. By a well-planned strategical pight march may be out-flanked, or a position enemy may be out-manked, or a position seized which would have been denied and defended by the adversary if he had real that the movement was being made or that the attack was coming A hostile army may thus be placed in such a posttion that the enemy is obliged to fight un der unfavorable conditions, or a com der placed in an embarrassing position by some unforeseen development, may extricate himself by transferring his forces to a distance under cover of the

A hight advance may be used to gain the recoil a ground from which further progress will be made in daylight, the troops being deployed for attack at the outset and not in march order, and in such cases the attack would usually be made as soon as it is light

An assault may be actually delivered during dark-ness, but the hazards of such a proceeding are so great that unless the conditions of a fire fight with the enciny have already proved adverse over the same ground in daylight, or are almost certain to be so, it is usually better to accept the proportion of losses by the enemy's fire which may be expected in a struggle for supremacy under normal conditions by day, trusting to gue and rifle for decision, than to endeavor to gain the point by the bayonet, the grenade, and hand-to-hand fighting, the only methods which can be relied upon in a nocturnal métée. In cases where a night assanir is considered imperative everything is done to avoid alarming the enemy until the attack can close Rifles are not loaded, though magazines are charged and cut-offs closed, the troops are given strict orders not to fire without a distinct order, bayonete alone to be used until daylight makes it possible to aim with effect; absolute silence to be maintained until the moment of assault, the advance to be carried out quietly and without rattling of acconterments. No smoking is permitted, no matches to be struck. If men come across obstactes which cannot be easily crossed or

cleared away they must lie down until a passage can le. If hostile scouts or patrols are encountered an endeavor must be made to capture them withou

en all is said and done it should be extremely diffi cult, even with all these precautions, to surprise an enemy who in view of the various reasons for night operations will presumably be on the londout for such methods of attack. Science will be pressed into the service of the defense and the occupants of a position will most certainly endeavor to turn the tables on their assaliants, converting night into day at short notice by causing the latter to be exposed to one form or another of artificial light at the supreme moment, while they themselves remain covered by the darkness. Star-shells have been found exceedingly useful against savage enemies, but a better illuminant still is the perachute-

Searchlights fired by infantrymen. Illuminating grenades disclosing a charge. Searchagnis ared by minimity men.

An illuminating remnal (flake, petent) is fred from a rifle. Four of the just burst in the air and their lights, 'beld' by parachutes, are falling.'

On the foreground have illuminating greated on their rifles, ready for the petent of the shoulder, but its butt is rested against the ground the regular would be rether too much for the man's shoulder.

light. This is fired from a gun like any other projectile, but of course with only a small charge of powder, and bursting above an enemy, develops into a parachute suspended in mid-air and showing a brilliant light which reveals during several minutes all that is going on beneath

ed and well-equipped force would of conbe provided with searchlights of a portable description in addition to the star and parachute shells. These and admitted to the star and paraceute sacis. These searchilghts would be especially useful to enable the arrillery to play on the assaulting columns with telling effect, and without them the guns would be of little use in defense by night. They would be posted, under the orders of the arrillery commander, well to a fank of the guns for which they are to "make daylight," at of the guin for white day in the protected from the enemy's fire by entrenchments, and would not be turned on until the enemy had been reported as advancing to the attack. As a means of ported as advancing to the attack. llluminating the immediate neighborhood of a positi another form of parachute light, on a minor scale, has been invented. This is in the form of a granade which can be freed from a rife, the but resting on the ground, to ranges of from 80 to 1,000 yards; the floating light burns from 30 to 45 seconds only, according to its sless, but the grenade has the great advantage of being very portable, weighing only 14 ounces, the firing-rod meet with it weighing another 4% ounces. It can be use

in positions and circumstances where either se light or artillery for firing the star or parachute she would be out of the question.

TO THE SECOND OF SECOND SECOND

For the discovery of strategical or tactical night marches it is probable that dirighles, furnished with electric lights dropped by wire from a considerable height and then switched on and off, will be successfully employed.

#### Annual Report of the Commissioner of Patents

THE report of the Commissioner of Patents for the finest year ending June 80th, 1918, states that the fine that time there were of 1960 applications for mechanical patents, 1,869 applications for design patents, 172 applications for relaxes, 7,063 applications for trade-marks, 262 applications for Inde-marks, 262 applications fo

trade-marks, 820 applications for laues, and 344 applications for prints. There were 38,754 patents granted, in-cluding reissues and designs, and 5,166 trade-marks, 664 labels, and 254 prints were registered.

The number of patents that expired was

21,427. The number of allowed applications which were by operation of law fortions which were by operation of any sor-feited for non-payment of the final fees was 6,970. The total receipts of the of-fice were \$2,082,490.23. The total expendis amounted to \$1,924,459.42, and the net surplus over expenditures was \$158,-030.81, making the grand total of net surplus of receipts over all expenditures \$7. 290.103.57

re was a slight decrease in the volume of business during the last fiscal year, the total number of applications for patents for inventions, for designs, for of patents, registration of trade marks, registration of labels, and registration of prints, disclaimers to patents, and appeals on the merits, is 80,084. The total of all applications for the fiscal immediately previous was 81,459 for the same period, which shows a deer 1,375 applications received.

In this, his last report as Commissioner of Patents, Mr. Moore again refers to recommendations which have appeared from time to time in his previous reports and which will be heartly indorsed by every inventor and attorney who is at all familiar with the Patent Office and its administration. Once more it is ursed that a substantial increase be made in the sal-aries of the examiners, and once more the need of larger and more commodious quarters for the housing of the Patent Office is pointed out. "The Patent Office has long since outgrown its present quar-ters, and in its present overcrowded and unmanitary condition is not calculated to inspire or encourage in its employees the

best or most efficient work. The desks se together in many of the rooms, and the ssity for working under artificial light and among dusty files' reduces the average of efficiency among the employees and puts the office at a disadvantage in that

#### Circular Saws of Paper

PAPER is at present used for all possible purposes in the industries and in all possible forms. It has even been possible by means of compression to give it a degree of hardness comparable with stone, so that it can be used as building material. The latest use for paper ever is perhaps the most peculiar. According to a European journal a factory is said to exist in Eugland which is manufacturing circular saws from paper. These paper saws are used for the manufacturing of fine furniture recent These paper saws are used for the manufacturing of fan furniture, veneer and other thin plates of wood, which must be treated especially carefully. Some time age otecular saws made from drawing paper were shown in an English exposition. The saws were driven by an electric motor and produced fus boards, which has been saw the saw of the saws were driven by an electric motor and produced fus boards, which saw the saw of the saw were driven to saw the saw of the saw were driven to saw the saw of the saw of the saw were driven to saw of the saw of

rs made in this way are so smooth that et makers can use them without further

card index plan, is most intere A couple of years ago the undersigned sugg similar plan to a couple of American publishing houses, ne was probably not then right.

It is not too late yet. ARREL G. S. JOSEPHSON.

#### Proposed Method for Clearing Channel or River Bars

To the Editor of the SCIENTIFIC AME

To the montor or the Schemitto American to not appear to be afraid of ideas because they are now or big or even grotesque. So I am venturous enough to make the following suggestion to you:

Why not, below the bar of a river (which it is ed to clear away or through which a channel is to be cleared or kept clear) place a number of pipes or a network of pipes, perforated as necessary. Then (from the shore or a ship) keep up a constant pressure of water (or air), which would cause a constant pressure. at the perforations. I assume this pressure could be

made very great.

By this means not only could deposit of material over a determined area or a channel be prevented, but I think the area or channel could be cleared of deposit. think the area or channel could be cleared of deposit.

The area or channel, once cleared, could be always kept free from deposit.

When an area or channel is to be cleared the pipes or network of pipes might gradually be covered a work proceeds; when the area or channel is once cleared, the pipes would be stationary.

F. C. CONSTABLE, M.A.

Wick Court, near Bristol, England

#### Boiling Volatile Liquids

To the Editor of the SCIENTIFIC AMERICAN:

It may be interesting to note that volatile liquids such as benzine, carbon bisulphide, ether, etc., may be belied over a naked flame with impunity to danger by simply covering the mouth of the receptacle with a wire gause. The gause should be about 20 mesh, and large enough tend an inch or so over the edge of the re

The vapors will pass through the gause and may be lighted (if so desired). The flame will burn above the gause, but will not pass through it and ignile the bulkcontents. If, for any reason, the flame is to be extinguished, then momentarily cover the gause with an nalseaton hoard SPENCER M. GOUDY.

Philadelphia, Pa. [While the method described above might prove very valuable under certain conditions, it must not be considered absolutely safe. It is always dangerous to handle inflammable volatile liquids in the presence of a naked flame, and if the gause should be sufficiently beated by the burning vapors above it the flame would leass through to the vapors within the receptacle. #### Grafting Performed by Nature

To the Editor of the Scientific American:
I wish to offer currection of a blunder made by one

of your correspondents in issue of Soptember 20th, entitled "Grafting Performed by Nature." The photo depicts a very common sight all over the West Indies depicts a very common sight all over the west holder and troplead America, including extreme southeast Flor-ida. It is the ficus aurea, or wild fig, which frequently starts in life as an epidendron upon palmettos, mastics or any other tree upon whose trunk the seed happens to be planted by some passing bird. The seed sprouts, and probably assisted by the bird dung, soon reaches the ground with a root, at the same time throwing out roots in the crevices of the bark of its host, and o surrounding the entire trunk. It is not a parasite like the mistletoe, but feeds from its own root system without sapping the bost

#### New Detector for Wireless Telegraphy To the Editor of the SCHENTIFIC AMERICAN

e of the readers of your magazi Thinking that son would be interested in a new detector device for radio work, I submit herewith the following:

mano operators are constantly on the abert for new detectors, or some new scheme to improve the efficiency of those in use. The following is a device which the writer has used with success and which embodies both great empativeless: and ability to withstand heavy status or jarving. Radio operators are constantly on the slort for new

With the fifth of the first of

Using the ordinary detector stand, place a piece of unslybdenite on the lower contact plate and on this molybdenite place a lump of allicon. A firm contact may now be made on the silicon, and when once adjusted will not need further attention.

This arrangement serves for long distance work, and in fact appears to have all the sensitiveness of silicon without the usual inconvenience of constant ad-nt. No battery is required.

Washington, D. C. JOHN S. DEFORMST.

## The Business Side of a Humane Animal Trap

To the Editor of the SCIENTIFIC AMERICAN:

In answer to an article written by George Foster Howell in your September 13th issue, in which he sets forth that there ought to be a humane trap invested to forth that there ought to see a numane trap; invested to prevent the torture of wild animals, I quite agree with Mr. Howell in his idea of the much needed want in the shape of a humane trap to prevent the torture and crueity of wild animals that are caught for their furs

The idea of one spending his money to gain thanks and gratitude from humane people the world over may look quite encouraging to one who is looking for notoriety, but in the matter of dollars and couls it is quite another thing. Inventing a humane irap which would be more expensive than the old steel traps would prohibit the trappers from buying them, unless they pronout the trappers from outling them, unless they were compelled to do so by a national law enacted. Though a humane trap can be invested that would simply detain an animal until he was taken out of 11, without any further torture, probably the trapper would nail them to the cross before relieving them from the

It is one thing to say what ought to be done and another thing to do it. Now to invent a humane trap is a very easy matter indeed, but to put it on a stubborn has very easy matter indeed, but to put it on a student merket is quite another question. Now if the Massa-chuselts Society for the Prevention of Cruelly to Ani-mals or any other body of humans thinkers would put their shoulders to the wheel and see that there is a national law enacted to compel trappers to use a ane trap, I would be one of the first ones to invent

and have ready for the market a trap for this purpose.

Glenbeulah, Wis.

J. Diehl.

#### Flagging at Grade Crossings or of the SCIENTIFIC AMERICAN:

In view of the great number of railroad accidents recently, everyone is interested in measures to reduce the loss of life. The other day a well-known artist

and his family were killed at a grade crossing protected by a flagman. Apparently the fullure of the flagman to properly guard the crossing has not been investigated further than to find out that he carried out his duties

The idea would naturally occur that the means us by flagmen to warn the public were better suited to the former days of slow locomotion than to the rapid rate al which automobiles now travel. It would seem that there is liable to be confusion in the minds of motorisis as to the meaning of the white flag, which the flagman waves as a sign to the public that a train is

white flag is usually understood to mean free-rom danger. Customarily, when a highway is dom from danger. don from anger. Concentry, when a nature, and under repair and flagmen are used to conirol the irrific, the flagman waves a white flag as a signal for the traffic to pass, and a red flag to hold up the traffic. This was the system used on a road near to where the faial accident occurred. It seems to the writer that the confusion arising from a while flag in one place meaning one thing, and in another place meaning just the opposite, may have been the cause of the fatal lent referred to. At any rate, owing to the prevalling uncertainty, some cautious motorists are in the habit of slowing up before crossings where flagmen are employed, and waiting verbal instructions from the flagman before attempting to cross.

It may be necessary to continue to restrict the use of the flags as signals to the engineer, even though the flagman is stationed at the crossing for the essen tial purpose of guarding the public. It would seem, however, that the waving of the white flag might be however, that the waving of the many magning or easily discontinued and the red fing reserved only for cases of emergency. Surely, traffic policemen have no trouble in making themselves plainly understood by simple motions of the hand, and it might be that the flagmen could similarly indicate to the public at the crossings whether it was safe to proceed or not. At any rate, some attempt might be made to improve on antiquated system at present in use by flagmen at railroad crossings, so as to accomplish the purpose of preventing accidents at these crossings. Surely if the preventing accidents at these crossings. Surely if the system of flagging a trail at present in use leads to confusion of the public, instead of becoming a protection, the flagmen might be a meanes and accident continue to occur at crossings which are supposedly protected by flagmen. New Haven, Conn. TRESCRIPE H. LOW.

#### The Ten Greatest Inventions

WillCil are the ten greatest patentable inventions VV of the just twenty-five years? to have your selection We should like

The vote called for in the SCIENTIFIC AMERICAN of Seplember 27th is coming in from all parts of the country. The principal of the Oley Township High School, Oley, Pa., submilted the list of forty inventions to his scholars and sent in their vote. The Editor wants mor such school voles. Scholars will find the question volv interesting. Here is the list taken from a dozen es Interesting snys in the Inventors Prize Contest

Acetylene gas from Kodak carbide Liquid air

Mercury vapor lamp, Monomii Burbank's works Motlon pictures Calculating machines Pasteur's work Color pholography Phonograph Concrele (reinforced). Photo engraving Chanide process. Picture telegraphy. Pnenmutle Hre Dictograph Diesel engine Producer-gas Dirigible. Preservation of sugar-Electric car. producing plants Electric furnice Rudlam Electric welding. Submarine bouts. Transmission and transforming of alternating Firstlen of ultrogen Flexible photo-film High-speed steel. current.

Tungsten lamp Turbine (steam). lamp. Induction moto Welsbach hurner Wireless telegraphy Internal combustion enging X-ray machine

One of our readers objects to the list as follows:

To the Coulest Editor of the Scientific American.

Although not a competitor for vonr "Ten Grentes' Inventions" prizes, 1 have followed the progress of the contest with great interest

Having been in louch with the development of the industrial arts for a unmber of years, both as a member of the Examining Corps of the Patent Office and us a practising attorney, I must say I mm surprised at the list of "Greatest Inventions" published on page 243 of your Issue of September 27th, 1913 Out of the number of essays which were submitted, many must have been good, and I am at a loss to undersland why. In compiling this list, you should have selected as among the twelve best any essay containing items

as among the tweet next any essay containing terms us absord as some of those mentioned.

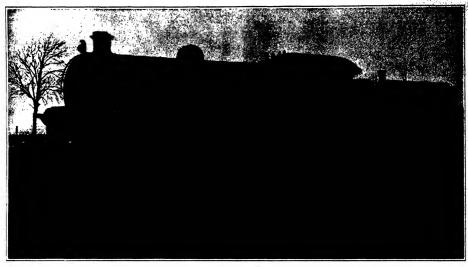

One of these items, the "phonograph," was specifically excluded by the terms of the contest as contained in the original amountement. Several of them, as, for example, "Burbank's works" and "Radium," are not pulentable inventions, and hence not cligible. such as "lucundescent lamps" and "Internal combustion engines," were in use prior to the twenty-five year period Still others, as, for example, "Liquid air" and "Monorall," are of purely scientific interest, having substantially no industrial application. And there is no class of apparatus known by the name "Koduk," this word being merely a trade name used to designate the goods of a particular manufacturer

Il is inconceivable why you should confuse your readers by including such items as those referred to above, which can be aptly characterized as foolish, while omitting such a thing as the modern type-setling This is universally recognized as the most marvelous mechanical inventions of the age. and I happen to know of several contestants who in chided the linetype in their list, without question.

I suggest for your carnest consideration that you examine again the essays submitted, publish a revised list of items, eliminating all "freaks" and including more real inventions, and then ask for the opinion of your readers. This, I believe, would be productive of more satisfactory results. J Hanson Boynen utisfactory results.

Washington, D C Apparently Mr. Boyden has missed the point. The list does not represent all of the essays not necessarily the best of them. Which are the best is a matter for the Judges and not the Contest Editor to decide The selection of essays was unde to show the wide diversity of opinion on the subject - As explained when the list was first published, it includes some which quite cridently are not patentable and some that do not properly belong within the 25-year period, but the voter must decide for himself which should be avoided on that score. Typeselting machines did not happen to be listed in any of the twelve essays, but if in the voter's opinion they are eligible, let him include them and any other inventions of his choice in his list.

Make your own selection of the ten best inventions and send them to the Coutest Edilor before the 18th of October. The result of the vote will be published in the Scientific American of November 1st. This number will also contain the essay winning first prize and the announcement of the successful contestants.

New type of English locomotive.

This incomption, designed at Charlestenburg, has eviluders of double the length of the stroke in which the flow of steam is in the same direction within the same eviluder spaces

#### Interesting British Locomotive Development By Our English Correspondent

284

THE interesting locomotive illustrated has recently been introduced into the heavy express service of the North-Eastern Rallway of England, which system. along with those of the Grent Northern and North British raliways, forms the East Const Route from Lon-don to Scotland This engine, built at the railway don to Sotiano Tink eighte, unit at the railway shops at Darlington, has six coupled wheels, and a four-wheeled leading bogle, and it is fitted with the Stumpf "uniflow" or "unaflow" apparatus, according to the designs of Prof J Stumpf, of the Technische Hochschule, Charlottenburg The fundamental feature of the Stumpf engine is the extraction of the energy

stuntly lu one direction from the not inlet ports to the relatively cold outlet In the ordinary steum engine, the flow is of course, reversed at the stroke and each exhaust stroke During the exstroke During the exgines the clearance space surfaces are cooled down by the cold wet steam, and as a result the next incoming volume of hot live steam suffers considerable initial condensation In the Stumpf engine this cooling of the clearance surfaces is avoided, with the result that initial condensation is almost entirely absent. Hitherto the avoidance of the initial condensation has been attempted in two different ways, namely, by superheating and by compound ing. In the first the steam is heated above its evapor ation point to such a gree that the cooling effect of the eximust steam is no sufficient to lower the tem perature of the steam to the condensation point. In compounding, the endeavor is to reduce the range through which the tempersture in each cylinder

for the Stumpf system that it removes the necessity for superheating, and that in a single expansion stage its steam consumption does not exceed that of compound and triple expansion engines. The exact form given to the Stumpf cylinder differs, of course, according to the nature of the engine for which it is intended. In gencrei, however, it is double acting, with an inlet port at each end and a common exhaust port at the center. The exhaust port is constituted by a series of holes drillied round the walls and leading into an exhaust belt formed integrally with the cylinder casting. The piston employed is of exceptional length and fills ap proximately half of the cylinder volume. In fact, at In fact, at the end of each stroke one or other of its edges is just clearing the ring of holes and allowing exhaust to take place. It is thus clear that each half of the cyli

volume has to deal with the steam from only one inle port. It will also be exthered that as the total area of the exhaust port is large the period of exhaust extends from a short time before the end of the stroke is reached until a short time after. The bulk of the one stroke is thus occupied with the admission and expansion, and the bulk of the other with the compres soo, and the bulk of the other with the compression of the steam. The period of exhaust covers one tenth of the stroke each way, so that admission and expansion occupy nine tenths of the stroke in one direction and ression nine tenths of the stroke in the other ction. The North-Eastern engine has cylinders 20inch diameter and 28-inch stroke. They are about twice as long as cylinders of the same stroke but of the ordinary pattern. The pistons are hollow castings with spring rings at each end. As already stated, they

act as exhaust valves and uncover the central ports when 10 per cent of the stroke has been completed. The admission of steam to the cylinders is controlled by piston valves placed on top and actuated by

# Mechanical Baseball Bulletin Boards

#### Reproducing Hits and Plays in Miniature

U NDOUBTEDLY a sight which must amass every foreign visitor to America, are the great crowds of baseball enthusiants clustered the great crowds of baseball enthusiants clustered around the builgetin boards of important newspapers, watching, enthresiad, the posting of the score that indicates the progress of an important game in some distant city. Such is the enterprise of our great deililes, that they are no longer contant with gratuitously posting merely the score by innings, but to reproduce on an animated board the actual plays that are made. For nearly twenty years inventors who realized the enormous popularity of baseball and the commercial success that awaited the man who could derive a simple and efficient way of reproducing the events of a distant game, have tried to meet the demands of the newspapers. Only recently, however, has the demand been mot. It is the object of this article to show some of the earlier attempts which were made to provide realistic builetin boards and then to describe the board which has been mort successful.

make to provide reasonic fluident hours and the medicarithe the board which has been most successful. The buildin board which is shown in Fig. 1 is entirely illuminated and hence is most effective at alght. The positions of the players are patitived on temporareless. Behind self-transparences are patitived on the players are patitived on the players are patitived on the players of the self-transparence of the control of the players are patitived on the blank players of the self-transparence of the players of the self-transparence above, the building board is of as of the building that the players of the players of the players of the standing of the clubs in the lesques to which they belong, the umpires, etc. Some of the information conveyed by the board is of a transferry character, and other information more or less first. Thus the events in the field are necessarily changing constantly, whereas such facts as "Game Playing at New York." "Attendance 23000," and "National League Standing," etc., are permanent. Therefore the inventor has supplied two sets of keys for his switchboard. One set of keys when depressed remains depressed and is used for conveying the more or less permanent information referred to; the other set of keys is retractile, and is used to indicate the position of the ball at any given moment. As soon as the finger is retractive, are retractive, the light which it con-

trols is extinguished. Electric lights are provided not only behind the transparencies indicating the infletid and outfield positions of the players, but also to indicate the location or he ball at every instant of the game's progress. A goog is provided to announce the base hits. When the game is about to commence, the operator at the keyboard lights up the "Score by Innings" transparencies of both citus, also the places for the runs, the club names and players' titles. As soon as he readvise word that the game has commenced, he depresses the key which controls the current to the "play ball" transparency, which is lighted up and remains on until the game is called. When the game is called when he recotres word which silteninates the word "Unpiress" and when he recotres word which of the unpires is to act, he depressed keys which illuminate the unpires should make an error and the single's should make an error and the states. In the state, the setting unpires's should make an error and the

SARSHIP TO THE

name is displayed in green lights. At the bottom of the bulletin board at either side of the center will be noted panels bearing the letters "LF," "CB," "RF," etc., which obviously designate the positions of the players. The names of the players are to be fashed opposite the letters which designate their team positions. Two tables or names are required, one for each team. If the club represented at the left center is in the field and the other club at hat, the operator pushes down the key which it-luminates the name of the player at bat and the position

Fig. 4.—A board in which amali dummies of the players are used.

be holds in the club. As a result a white light is made to fare up. If this man makes an error, the fact is communicated to the spectators by extinguishing the while light and illuminating a green lamp. As the successive players take their places at bat, the keys are operated to illuminate their names in turn and to record

The course taken by the ball is indicated by lamps placed in the field. These ball lamps are under the control of the retractile keys. The course of the ball from start to finish is thus accurately indicated and represented. If, for example, the umpire tosses the ball to the pitcher, a samp right bahind the pitcher flares up and goes out as soon as the ball is thrown If the batter hits the balt, the lamp immediately in front of the batter is illuminated by the depression of the proper key. If the ball should be eaught by the catcher, then the catcher's lamp will flare up. Nimitarly the position of the ball in the hands of the outfielders is indicated, as well as its position when it is batted between two outfielders or infielders. If a player puts out a man rying to make any of the bases or to score, the lamp at the station of the player is lighted and also the lamp at the base where lie man was put out in order to indicate what man was put out and what player put him out.

One of the pioneer basebuil bulletin boards which is frequently cited against applicants for patents in this class of invention, was patented on May 6th, 1880, by Edwin A Grezier and Frank P Anderson 1ts general features are shown in Fig. 2. Along the line of the diamond is a groove in which a number of cords or These cords and endless belts are arranged to run their supports constitute a mechanical conveyer. They pass through the board near one corner of the disond (near third base in Fig. 2) and are worked by handles behind the loard Each cord carries one or more wire clins extending out through the groove in the face of the board and carrying a tag or marker. The various markers indicate the players. By means of the cords the markers can be moved along from base to No attempt is made to show what becomes of bull if it is batted to one of the outfield positions; only the actions of the base runners is indicated.

The aquastrus shown in Fig. 3 does not give nearly we vivid a representation of the actual occurrences on the distant diamond as the devices thistrated in Fig. 1 and 2. Indeed, it is little more than an annunctant The progress of the game is disclosed by means of plates which swing around on pivots, somewhat like the dampers in a stote-pile. The numeral 5 in the illustration under the heading "Batter" indicates clearby enough how the plates turn. A simple train of general driven by a weight, turns the plates. A detent holds the plate in pestion until the numeral which it bears

is to be displayed. The deient is withdrawn by means of an electromagnetic apparatus operated by a key There are as many keys as there are plates

In the bulletin board shown in Fig. the actions of the players, rather the positions of the ball, are resistated by presented Ac our liberation shows, the bulletin board is slotted in The manufacture of the source of the sourc

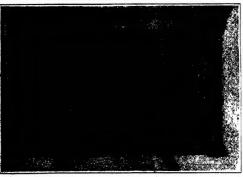

Fig. 5.—Front of the most successful board as it is seen by the speciators.

In Figs. 5, 6, and 7. It is to be found in front of many averagers offices all but hypotating crowds that keep the potent hard presents of a distant game with attached detail and rentism. Indeed, it is not unusual to hear cheers rishing from the assembled "fans," when they watch the induced distillation of a particularly brilliant plan on this simple but linguisous bulletin board.

In this particular board the activities of the base runners as well as the career of the ball are represented, and therefore it is a distinct improvement over the toventions previously described.

Fig. 5 is a front view of the board us the spectators see it. In Fig. 6 the covers N, N', N', and N' have been removed to show some of the mechanism. Fig. 7 shows the back of the board.

Between the bases and the home plate grooves are cut. In these grooves four endless challes B travel over

spreckets. The approximate grown except diameters C, two for every grown except that extending between the home-plate and first base, in which case one player indiction by provided C only one of the two indicators carried between first and second base, second and third base, and third base and the home plate is visible, the other being concealed by the covering strip N, N, or N, as the case may be. The spreckets are driven from a small

electric motor 4, the current to which can be cut in or out by means of the switch F The motive power for each chain is The motive power for each chain is controlled independently from the four keys E As may be supposed, each key controls one chaln and its sprockets in Fig. 6 a player indicator is shown at the lat Suppose that he makes a base hit; immediately the proper key E is depressed, and the player indicator travels with its sprocket chain to first base. Suppose that this player tries to sten! second but is caught between the first a second basemen. The sprocket chain traveling between first and second base is stopped by means of the key E, so that the player indicator remains between the If a telegraphic report is received that the player has reached second, the chain is started again, so that the fudicator is carried to the second base other hand, it is reported that the player has been forced back to first base, erator of the bulletin board turns a handle D, and the sprocket chain carry ing the player indicator is moved back to first Hand operation is necessary in this case because the electric motor always drives the sprocket chains in the same forward direction

Two indicators  $\ell'$  are carried on the challis between all the bases except the home plate and the first base. It will be observed that an indicator be exhibited to the expectators between bases. As soon as it reaches the base toward which it is moved, the operator presents his key  $\ell$ , stops the chaln, so that the Indicator remains in sight covering the base. If the indicator is to be advanced to the next base, it is covered in the next indicator, which promptly status on its journey, the first indicator themperoring behind its covcring strip h,  $h^*$ , on  $h^*$  as the case may be Suppose that all the bases are full. In

Suppose that all the buses are fail. In that situation the players are usually off base. They are held thus by throwing the awitch F which cuts of current from the motor A. If a mun is enight between bases, the bundle D works the indicator lunckward and forward to indicate his prediction.

to his base and disappears, and his misfortune is recorded on the secretosural bin if he succeeds in roughing the base, the switch F is thrown again, so that the motor is again supuled with current. Simultaneously the men on the other bases are advanced in position assuming that noise is put out. From this it follows that the switch F is used primarily when all the bases are h.

The mechanism for reproducing the antics of the ball remarkably fixable. The white balls are employed One of these  $\theta^*$ , a real baseball, moves about on the fout of the beard in full view of the spectators; the other  $\theta_*$  moves about at the back of the beard. The ball  $\theta$  may be called the master ball, and the ball  $\theta_*$  in front of the board, the exhibition ball. Each ball is moved about by the said of three cords meeting at a common point. The cords in frunt of the board are very this and so polored as to harmonise with the back ground. Hence they are not at all visible. The master

ball G (Fig. 7) is attached to the cords, J, J, and J. The exhibition ball G in front of the board is controlled by the cords M, M, and M. The three cords J, J, and J puss respectively over drums K, K, and K; and the cords M, J, and M; controlling the ball G, pass respectively over the drums L, L; and L. The two sets of drums are controlled by counterwights.

drums are controlled by counterweights.

The master hell of at the back of the board is maniphiated by means of the handle H to which it is attached. If the operator is told that the ball has been batted to center field, he simply carriers the master ball G by means of the handle H from the home plate to center field, simultaneously the exhibition ball G in front of the board is moved by its strings M, M, and M in the corresponding direction. Thus every one of the movements of the ball telegraphically reported is duplicated on the board. If the pitcher twirds an outcurre it is a simple matter to show the ball curring out markedly,

3 OUT ALL S 3

Fig. 6.—Front view of the board with covering strips removed to show the mechanism.

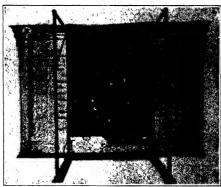

Fig. 7.—The back of the board, showing the method of operating the master hall.

So, too, it is possible to throw the ball with lifelike effect from the catcher to the first baseman or to any position in the field. When the ball is not the operation, the counterweights on the drums drop to their lowermost positions and hold the ball in the pitcher's box.

#### Rapid Telephotography By Dr. Robert Grimshaw

RECENTLY Prof A Korn, whose work in connection will telephotography, or the transmission of photographs by telegraph, is so well known, and who has solved practically the transmission of illustrations and handwritting ever long distances by wite, reed a paper in Vienna on ingrevements made and probable in the fine of rapid transmission over long distances; with the discovering the continuous properties of the transmission of kinematographic dim pictures. The most important preblem to solve is

increasing the rapidity of transmission. This is limited on the one hand by the insirth of the apparatus soot to receive and to transmit; but much more by the capacity of the circuit to transmit the signate of multipless which together make up the picture reserved.

。中央NEEEELLANG 生生化。1980年中央1980年中央1980年

October 11, 1911

primes wincin conjecture mass up the picture reserved.
For sendings through shert floss the speed which has hitherto been attained about affects inslustes for a picture 13 by 15 centimeters (5.12 by 7.69 inches) can be considerably increased, as the sending and receiving apparatus permit this; but the main advantage in phototelegraphy is the ability to beet the post, which comes into play only on long lines such as Berlin to Vienna, Berlin to Paris, etc. This would permit illustrated papers to print in that morning editions pictures which would not have resched them in time by mail. For this reason there would be no use in trying to increase the rapidity of operation of the sending and receiving apparatus, without having first increased the expectly of the line. This is a marked capacity of the line. This is a marked capacity of the lessending of imberator.

capacity of the line. This is a marked hindrance to the sending of kinematographic pictures, where it is necessary to send a great number of pictures one after another by telegraph in order that they may be assembled at the receiving end in film form.

Working with Herr Bruno Glatsel, Frof. Korn has made the first attempts at transmitting a kinematographic series of pictures; and as a result it appears that where there is an hour at disposal for the transmission of a series of 20 pictures, this can be done.

As the time required for the transmission of a picture 13 by 18 centimeters is 15 minutes, 11 is evident that where much greater speed is required, one cannot expect too much detail—so Prof. Koru has contented himself with a comparatively simple subject—the gestures of an sector. Four of the pictures immediately following each other were brought together on one plate, and this was sent in 12 minutes; so that for a series of twenty such pictures an hour would be taken up.

The pictures received are then arranged in the proper order of sequence, and transferred to a kinematographic film, which enables their being thrown upon a screen as a kinematographic picture.

This permits giving an occurrence which takes place at midday in Paris, in a Berlin "movie" on the next morning; and when the matter is of importance, so that the entire night can be devoted to its transmission, a good kinesactographic representation may be given the next morning.

These experiments also throw light upon the question of whether or not the problem of television or seeing by tele-graph can be solved in the near future. A series of twenty kine pictures takes about 20 minutes of actual occurrence, but for the transmission, at least an hour is mecessary. To send as fast as the actual occurrence takes place would require 1,200 times the present speed of transmission. For this reason, Prof. Korn gives it as his opinion that telegraphic vision can in the present stage of the art be accomplished only by the use of a great number of electric circuits. The principal hindrance to the accomplishment of this desired end is the enormous amount of capital which would be required.

#### The Food and Drugs Act Guaranty Label

IN an, interesting article published in Take Nation's Business by the Chamber of Commerce of the United States of America, Dr. Carl I. Alaberg, chief of the United States Ruceau of Chemistry, Department of Agriculture, calls attention to the futility of the guaranty label. Many persons misconstrue the significance of the label and believe that the labeled goods have been subjected to analysis by the Department of Agriculture. The Food and Drugs Act One on trequire the manufacture to employ the words "Guaranteed Under the Food and Drugs Act" or to place the serial number on this label. The words "Guaranteed Under the Food and Drugs Act" are resuly a guarantee of the manufacture to relieve the customer of responsibility should the goods be proceeded against by the Government.

coseded against by the Government.

Dr. Aleberg suggests the advisability of legislation providing for the denaturing of domestic food substances which are declared until for food end whisting the alipper may declare designed for use whelly in the arts.

#### Electrified Chickens—Electricity as a Grewth Stimulator

By the English Correspondent of the Scientific American

S OME time ago Mr. H. G. Wells wrote a delightful fantasy called "The Food of the Gods," in which he imagines a food which stimulates growth to such an

extent that the dimensions of all living things who feed upon it are increased are or seven times. Mr. Wells probably had no esseption that such a stimulating agent would ever be discovered. But it appears as the result of some very recent pears are the result of some very recent researches, that living beings may be greatly increased in size when subjected to proper conditions. It is true that no superior that the superior that it is true that no superior that no superior that no superior that it is true that no superior that no super

High frequency currents have long been used by the medical profession with hence foal results, but until recently the mere frings of the subject has been touched, Medical mon have been contented with a comparatively limited range of application. It has been reserved for Mr. T. Thorne Islate to show what great possibilities are inherent in the application of high frequency currents to blying things. For some time Mr. Thorne Baker has interest, promise the growth of pacterial and moses, but his latest work, aparl from its scientific interest, promises to have results of great the second of the provided of the provided of the second of the provided of the provided

commercial Importance. The latest experiments are concerned with lie influence of high frequency currents upon the growth of chickens, and they
are being conducted upon a truly coloseal scale.
Meeches Farm, Poole, England, is probably the greatest chicken farm in the world, and is the secue of these
est chicken farm in the world, and is the secue of these
est experiments. On this farm about four thousand
chickens are being grawn under the influences of the
electric waves. The results are truly actualising. The
chickens live in flats and over the whole building is
wound an insalted wire which is traveraed by the
high frequency currents. The apparalus which genetees the high frequency currents presents distinct
see that the outcome of unnerous experiments. Careful adjustments have to be made of the various electrical quanties entering into the circuit, before any offect is produced, but with a project adjustment of the apparatus,
most marked effects occur.

Chickeons living in the electrified flats reach, in five weeks, the normal weight of chickens three months old. And out of four hundred chickens treated in this way only six, and liness obviously doomed from birth, ided. In view of the farct that a fifty per cent deathrate is usual at this period of the year, it will be seen that this result is sufficiently startfling. Chickeons so weak that they could not stand up, and who in the ordinary course would infailiby have died, have been put in the electrified flats and become houlthy and

It is not only that the output of a chicken form is doubled by this process, but a considerable saving in food is effected. Only two thirds of the usual quantity of food is required by the electrified chickens.

The chickens are charged to such a high potential that a spark discharge occurs on presenting a fuser to the beak. From the schentific point of view the most interesting part of this work is the theory which explains Aov. high frequency currents attinuinte growth in this way. Mr. Thorne Buker is of the ophtion that the high requirecy currents attinuinte the blood circulation by lowering the viscosity of the blood. He has conducted experiments on the effect of high frequency currents on the flow of viscous fluids, and he fluids that the time of flow is decreased. The viscosity and losses some of the viscosity and becomes more mobile. It is not at present known whether prolonged elec-

It is not at present known whether prolonged electric action increases growth up to maturity, or whether its whole effect is to cause the maximum size to be sooner reached.

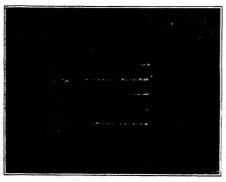

In certain quarters the application of high frequency currents to the growth of children is being contemplated, and the results in this field will be awaited with interest.

It is evident that we have here a method pregnant with possibilities, and its further developments will be rich in interest both in their scientific and commercial

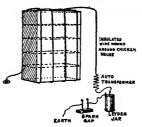

#### A New Language-teaching Phonograph

rgulff phonograph may be considered, in principle at a least, to be an ideal language teacher, but as a matter of fact its use has been very limited for this

purpose up to the present time. The reason why the advantages of the phonograph have not been widely made use of, lies in the fact that the spoken words as recorded upon the disks cannot be used alone for learing languages, at least by the general public, for we must not only hear the words, but have the same words in prints on that they are viable to the eya and at the

The electrified flats in which chickens are raised.

How the chicken house is wired.

same time have the translation into the learner's tongue. Inventors do not appear to have been able to combine a suitable device for carrying this out, and it remained for a well known phonograph and moving picture firm of Paris to solve the problem, with the instrument seen in our photograph as the result. Although very simple in fis idea, the apparatus was by no means an easy one to realize in practice, for what was required was to have a paper strip with the printed words and their translation pass along in front of the learner so that he can see them at the same time he is listening to the

Learning a language in a new way.

same words given out by the phonograph. Then after a little experimental work, a suitable mechanism was devised for currying this out. The paper band unrolls continuously while the disk revolves, and the right word always fills under the motal pointer placed at the center position. Should the device prove to be all that is chimzed for it, it will make a decided step in advance

in the matter of learning languages, for the price is which the reach of all, and it will now be possible to learn any language without the aid of a professor such as was heretofore indispensable in order to have a correct pronunciation ness of the "automatic professor" lies in the purallel action of spoken and printed word, both eye and ear receiving the impression at the same time, so that the memory retains the form of the printed word accompanied by its sound. In prin-ciple there is no limit to the number of languages to be barried by this method. At the start the constructors have brought out disks and rolls for English German and Spanish, but when the device comes into extensive use these will be followed by others. We need not dwell upon the advantages which the phonograph method has over the usual language professor Besides being polyglot, it saves much thus and is ready to be used on any occasion, without any of the usual drawbacks. The simplest form of the device consists of the phonograph and paper roll mounted upon a flat base for placing on a table. How-ever it is most convenient to have a suit-able place for keeping the numerous disks and corresponding rolls, and this can be

done in the more elaborate nymeratus which is seen here. The outfit for the Gorman language, for French learners, comprises two specially-propared language books, twenty-sky phonograph disks with records upon both faces, and fifty-two printed lands, each corresponding to one face of a disk. It is interesting to note that he first elements of music can be learned in the same way, and a set of disks and other material is already leased for this purpose.

#### A Warning Against Fraudulent Radio active Water

THE United States Department of Agriculture, through the Bureau of Chemistry, has besued the following warning to the public in regard to the socalled radioactive mineral waters offered for sale in

called radioactive mineral waters offered for sale in bottles:

"There are indications of the beginning of an attempt to perpetrate a great fraud on the 'uncitan nepole through devertibing certain mineral waters as possessing radioactivity. These waters, in some cases, are then from springs as a certain radioactive properties. Examination of many of these waters by the Department's specialists, indicates link whatever radioactivity they possess at the spring is due almost entirely to radioactivity properties. Examination of many of these waters by the Department's specialists, indicates link whatever radioactivity they possess at the spring is due almost entirely to radio activity. The belief long in which they water has been bottled a short time, it will possess paractically no radioactivity and the belief long into by many leopic that some universal waters used at the springs are more effective than ground that the beneficial effect of these waters is due to radioactivity. As the radioactivity disappears soon after the water is taken from the spring, any effect due to the radioactivity number he lost in a short time. If the radioactivity must be lost in a short time If the radioactivity number is due to regard with suspicion any water advertible and source in the water is the spring. As far as the correlated as possessing radioactivity, as far as the teaching results in the water at the spring, results this water dotting on asverticin, an attempting results have been point to asvertich, and the spring, results thus radioactivity for any length of time. The beginning of the content of the content of the water at the spring, results thus reducently for any length of time. The beginning of the water at the spring results in the radioactivity for any length of the content of the content of the water at the spring results in the radioactivity of any length of time. The beginning of the content of the content of the water at the spring results to the radioactivity of any length of the

bottled water, no matter how radioantive it may make even at the spring, retains this radioantivity for any length of the properties of the control of the c

It is said that 90,000,000 broom handles are used annually in the United States; one for each man, woman and child.

And the state of t

#### The Construction of a One-kilowatt Closed Core Wireless Transformer

Till advantages of closed core alternating current transformers over the rapidly disappearing spark coil and pureliable vibrator for wireless transmission lie in their comparatively simple construction, their

Fig. 1,-Assembling the "leg" of the core.

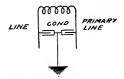

Fig. 2.-Diagram of condenser co ducing static strain in primary.

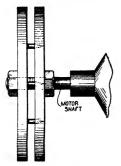

Fig. 3 .- View of the winder

high efficiency, their positive operation and their up standing under severe overload and physical abuse Almost all of the disadvantages from a constructional viewpoint are eliminated, so that the making of a very satisfactory transformer involves only patience and ordinary constructive ability

The inefficiency of the average experimeniers aerial

necessitates the use of a transformer of larger capacity than would ordinarily be needed if all conditions were favorable Under standard conditions wireless sets will ravorable Under standard conditions whreless sets will trainshit labut one mile for every ten watts of energy expeuded. By standard conditions is meant a well insulated nerial that is at least 100 feet above surrounding metallic or conductive objects. Correlative rounding metalite or conductive objects. Correlative with this is ground inviting a low resistance to high frequency currents is necessary. Water and gas pipes contrary to the usual belief do not always fill this requirement, and as the typical amateur's nerial is always more or less poorly insulated and his instruments improperly tuned, his set instead of transmitting one mile per ten watts, seldom averages half of that.

The question of the most sultable size of transfe to build for experimental use, is easily answered. The constructive limit in most cases is reached at the 1 kilowatt size. Dillicuities urise from bulkiness and extreme insulation which is necessary in sizes larger than 1 kllowatt. The cost of materials is an important consideration, and it might be well to mention that a 1 kilowatt transformer will cost bardly twice as much for materials as one of the ¼ kilowatt size. If there is any possibility of interfering with comm Government stations, a lower power should by all Government stations, a lower power should by an means be used and may be obtained by inserting an adjustable water rheostal or a choke coli in the primary circuit. The former type of current regulator be easily constructed by filling a keg with strong salt water, placing, for an electrode, an iron disk in the bottom and raising or lowering another iron disk in the solution. The amount of current allowed to flow will be found to be inversely proportional to the distance that the electrodes are apart.

The transformer will consist of the usual hollow rectangular shaped "closed" core of laminated from wound with a few turns of coarse wire and a large

number of turns of very fine wire. Upon the ordinary house lighting current (110 volts, 50 to 120 cycles) being introduced into the coarse winding, or primary, the magnetic action of the core will cause a current of extremely high potential to be originated in the wind-ing of fine wire, due to the ratio of turns. The great nce of potential at the terminals of the seco as it is called, is suff cient to cause the current to le between them and, if they are held near enough to gether to form an electric are of low density. By shunting a large capacity condenser across the terminals, a crashing white spark takes the place of the noiseless arc. It is this spark that is used in wireless transmission. A high tension conde

cussed in a latter part of the article.

If the transformer is constructed in accordance with
the directions given below it need not be oil immersed.
However, it is a good plan to immerse the transformer
in boiled oil in damp localities, especially near salt

#### Construction.

The core will be built up of annealed, soft iron strips. about No 28 A. W. G. of two sizes, measuring 14 by 2 and 6 by 2 inches, respectively. Two piles each 4 inches d. will be necessary of each size when compresses high when compressed, will be necessary or sach size. Two "legs" or sides of the longer strips should be built up to a height of 2 inches and in such a manner that 2-inch spaces are left altornately at the ends for the 6-inch by 2-inch cross places. This construction is given inch by 2-incre cross pieces. This construction is given in Fig. 1 and may be seen fairly well in one of the photographs. About 50 pounds of iron will be necessary for both sides and cross pieces.

The legs when assembled should be tightly taped and

ould be tightly taped and wrapped with oiled muslin cloth to within two inches of each end and to a depth of 1/4 inch. Oiled muslin cloth, available under the commercial names of Empire cloth and Linonite, when dry will withstand a puncture tes of about 1,000 volts per mil, although under heat and corona stresses it will deteriorate somewhat.

There are two well known methods observed in wind-

ing iransformers. One, by having part primary and secondary wound on each leg; the other by winding the primary on one leg and the secondary on the other The latier possesses several advantages over the form method from a constructional and economical view-point, but it is slightly less efficient. However, as this detriment is more than offset by such essential considerations as simplicity of insulation and design, the latter method of construction will be treated in this article

The primary will consist of eight pounds of No. 10 D. C. C copper magnet wire wound on one of the legs to a depth of four layers. A space of 1/2 inch should be left at both ends of the insulating sleeve so that there will be no dauger of the primary's sparking to the core. Consecutive layers should be paratined and insulated by several layers of the oiled muslin cloth insulated by several sayers of the olied musin citor as the static kick back from the secondary if a large condenser and aerial are being used, is sufficient to cause "skin" currents upward of 1,000 voits to be generated in the primary. In severe cases of this kind the kick back is sometimes strong enough to consparking with subsequent arcing and burn out in the

Fig. 4 .- Secondary partly assembled

Fig. 5 .- The completed transfern

fixtures, thus constituting a serious five hansed to the building in which the viruless plant is located. To alleviate the strain, a low-capacity, selectorype col-dancer constructed of glass plates, should be shunted across the supply mains and the constru conductory grounded to relieve any abnormal difference of possetial between the two supply lines or

must be recled into thin pancake-like sections-a task somewhat allayed by the proper winding machinery—a lathe preferably.

The square hole in the center of the section should be sufficiently large to allow it to fit snugly over the

Sectional view of the liquid of

core and insulation, about 2% inches by 2% inch When a lathe is not available, a simple winder may be constructed similar to the one in Fig. 3. This consists of a fan motor with the section winder botted to the end of the shaft. The winder or form comprises two disks of \( \xi\), such majle seven inches in dismeter upon the face of one of which are fastened four iron pegs spaced 21/4 inches apart. The wire is wound on over e pegs between the walls of the disks until a sec tion is formed 6 inches in diameter. Twenty sections should be wound in this manner. The size of the wire is No. 82 D. C. C. Nine pounds will be needed.

The sections upon being wound should be removed to

a pan of melted parafin and beeswax for impregnation. The temperature of this compound should never exceed 100 deg. Cent. or it will carbonize and lose its in The coils should remain in the insulating mixture for at least 15 minutes or until all air bubble cease rising. They should then be pressed until cold between marble slabs and taped with strips of bias between marties makes and taped with strips to one cut chied muslin cloth, ½ inch wide, particular care being observed that the wires do not become kinked and that their direction is definitely marked when they are taped.

As mentioned previously, there will be 20 section As mentioned previously, there will be an sections in all. As the secondary, output in volts is about 20,000 a potential difference of 1,000 volts will exist between consecutive sections. Circular, olied muslin cloth sep-arators 6½ loches in diameter should be piaced between the sections as shown in Figs. 7 and 8 to rethe strain between them.

There are several well known methods employe ting the secondary coils. The one, treated herewith, possesses the advantages of a higher efficiency than the others, and the strain between consecutive sec-tions is much less. Both end sections will terminate with an outside turn so that two of the choicest should

with an outside turn so that two of the choicest should be set saide for this purpose.

The core leg should be clamped in a vise and a sec-tion slipped on to within two inches of the lower end of the insulating sleers. A separator should then be placed against the section and the inside turn tongst under it. Observing the direction that this turn takes, another section should be lowered into position in such a manner that its inside turn rens in the opposite direc-

### A New Bookbinding Device

**発展を影響を開発する**など、対象を見れている。

WO big problems that have confront a encreasful solution in the flexing machine of which Charles W. Mears, ad-vertising manager of the Winton Motor Care-Company, Cleveland, is the inventor, patentee and owner

One of these problems is to secure a flat-opening book that does not involve the expense of sewing, and the other is to produce a book of coated paper that is free from the danger of tearing apart be-

When a sewed book is produced, each separate signature of the book must be separately handled on the sewing machine. This involves an expense of time and money that is so considerable as practically to prohibit the production of sewed magazines. In an effort to producflat-opening magazines, some publishers have put into practice a method of trimming off the backs and of applying glue to hold the separate sheets together. This is not an inexpensive process, for the machine that does this work requires an investment outlay of thousands of dollars. two-page sheet must depend upon a mershred of give to hold it in place, there is danger of pages falling out. This danger shred or give to noid it in place, there is danger of pages falling out. This danger increases with the age of the look, for give is an animal matter and rapidly de-

In the case of the book made of coated In the case of the book made of coated paper, even the expensive sewed method is not satisfactory. The reader's eyes fall upon unsightly needle holes and thread in the center of each section, and, if the book is handled considerably, only a short time elapses until the sections tend to separate from each other. The pracimpossibility of holding sections firmly together is due to the coating of the paper, which the glue readily The book then ceases to be a taches.

cempact unit.
These defects of book-making cau the production of the Mears flexer. This machine is designed to work in unison with folding machines and with presses deliver folded signatures, thu avoid the expense of intermediate handling of paper and loss of time. Timed in synchronism with the folder or the press, as the case may be, the flexer receiv folded signature and carries it through the open jaws of a pair of grippers until the closed back of the signature meets an adjustable stop.

The grippers then close on the signature and carry it down over a series of rollers, which bend the signature on a distinct line parallel with the closed The return movement of the grlp pers carries the signature once more over the rollers, bending the signature again in the same place, but in the opposite direction. The grippers then open and the flat signature is discharged into

At the point in the signature where th forward and backward bend is made by carrying the signature over the rollers, the signature sustains a permanent flex. Signatures are enthered in the usual man ner and are then made tato a permanen book by the cheanest and most substan sook by the createst and most substan-tial method, that of side wire stitching. In the reader's hands a book made on this method lies open flat, the pages falling readily to right or left, as the read

The inventor claims for his flaxer an The inventor claims for his flexer an entirely new result in book making—a flat-opening, permanently bound book that can be produced more cheaply than by any other process. On a recent run of 40,000 catalogs of four signatures each, the saving in manufacturing cost by this method as against that of sewing was

Various disse of signatures can be and sometimes sand paper and fine emery madeled on a single fitter, and it is possible to vary the distance of the bend This, of course, requires skillful handling. from the closed best of the signature to It is believed that some means may be destit the job. The adjustable stop is required to the signature of the signature of

### Progress in Landing Zeppelins

M ORE significance than to the loss of the "T. T" the "L. I." under conditions fatal to any aircraft should be attached to recent escapes of Zeppelins from their worst enemy—the danger of being smashed in stormy landings. The military "Z. IV.," returning from the army maneuvers, was evented by a storm from entering the ed at Leipzig. Toru from the hands of soldiers by a gust, it was violently raised. Two soldiers were killed, but nothing haped to the airship, which, fully manne with motors running, was instantly und

control in the air. The writer was privileged to see an in-teresting docking of the passenger ship "Viktoria Luise" with the Grand Duke of hessen and two princes of Greece aboard in a gusty wind blowing across the en-trance of the shed.

Extreme caution was observed and the latest developments in the art of land ing were shown. The ship, held by not more than twenty to thirty men, was bumored like a restive horse. The men on the ground held it on four bundi ropes, fore and aft, and by railings, fast ened to the sides of each car. Four heavy ropes with clamps to hitch to trucks on the docking tracks, were also manned for instant use. Gusts would alternately raise a car, forcing the men to let go. Running. they caught it again like an enormou football.

Those at the ropes simply slackened with the gusts. Two officers on the ground gave brief commands. The wind shift so suddenly that the men at the float ing rear end had to run, keeping pace with the swinging hull. But even the front car, resting and pivoting on its inflated huffer-bug, was occasionally dragged over the turf. After a heavy gust the rour of the rear motors would be added to the incessant humming of the forward one, and two of the propellers begin revolving. Captain, officers and engineers were at

Later (the serial sparring had lasted beyond noon) the steward was seen emerging from the passageway above the front car with some lunch. The ship was first worked toward the shed. tempt at entering proving too risky, it was taken back to the distant moorings, not to be anchored to the strong chain fastened to a buge "cannon ball" heavy socket, nor to four buried blocks by radiating cables, but to reach a water sup-

While it still bobbed in the gu long flexible hose was run into the 'hold' and the equivalent in water ballast of the passeligers' weight was pumped ab A rope-lined gangway was lowered, and during a quiet minute the passengers were safely landed, followed by the captain

Relieved of his worst responsibility, he turned the bridge over to the first officer. During a longer lull the ship was late quickly run into the shed with the help

of the propellers. "Z. I.," returning fro The military Silesia, was met by thunderstorms. Con trary to former methods, it sought refuge in the air, weathering heavy winds for eleven hours. Fleeing toward the north it cruised for two hours above Posen, pur sued by a chain of thunderstorms that extended to the Baltic. After the storm had subsided in Silesia it pushed through and returned safely to its starting point.

### Removing the "Shine" From Woolen Garments

W COLEN garments, especially hard finished ones such as serges, soon be-come shiny from wear and the problem ove the shine. Some tailors in doing this use a wire brush which oper-ates to pick up a surface resembling nap Various since of signatures can be and sometimes sand paper and fine emery

When you take Sanatogen you join hands with many of the world's most distinguished people, people who paid in tired and disordered nerves the penalty of success.

A vast company of Statesmen, Churchmen, Authors, Business Magnates, Social Leaders, etc., who took Sanatogen often on the advice of their physicians, have written of the gratifying results which followed. They tell us how, in times of mental or nervous exhaustun, Sanatogen instilled fresh vigor, rekundled energy and ambition, and made life and work once more a pleasure; how, when digestion was upset, sleep uncertain, Sanatogen sharpened the appetite, gratefully assisted assimilation, and promoted restful slumber.

Such experiences are freely told by people whose keen minds are not misled by imagnation, and who are not given to restumonial writing. Added to their evidence, moreover, as the authoritative pronouncement of trained physiciaus, no fewer than 18,000 of whom have recorded in writing their belief in Sanatogen and their observations of its aplendid restorative and upbuilding

effects.

The world's brightest intellects, the trained guardians of health, using, prescribing and recommending banatogen—is not that sufficient assurance that Sanatogen will help you?

### Write for a Free Copy of "Nerve Health Regained"

If you wish to learn more about Sanatogen before you use it, write for a copy of this booklet, beautifully illustrated and comprising facts and information of the greatest interest.

### The Industrial Need of Technically Trained Men-VIII The Possibilities of Railroad Engineering

By A. W. Johnston

[Mr. A. W. Johnston, the author of the following article, began his reliroad caree early forty years upo. Educated as an engineer, he was enyaged in engineering wor (Mr. A. W. Johnston, the author of the following arms, very conserving work mearly forly years ago. Reducated as an englewer, he was empaged in engineering work about Afteen years, and for the remainder of the time has been an operative and administrative effect. From 1889 to date he has been Division Superintendent, General Engerintendent, and General Manager of the New York, Chicago and St. Louis and St Railroad. Mr. Johnston is a charter member and past president of the America nusrous... ar. vonasion se e carrer mismor any puts pressons of the American Robert way Engineering Association, and a member of the American Society of Civil Engi-neers. He is a graduate of Massachusette Institute of Technology.—Entros.)

wanderer over the face of the earth. His training was largely in the school of experience. On his ability as a locator of prince, or his ability as a locator of railways depended very largely the office of the most flavorable preliminary theory of the most distinguished men in the general profession of engineering came thus promisence by their ability in locating and construction, but might be profession of engineering came thus promise in the results and, perhaps brilliancy, an exercise position on maintenance. Fructing rallways.

Some rallways of the earlier type, once

constructed and in operation got compara-tively scant attention from an cogineerling staff. Very often records of surveys ly. The first eight or ten years of and land plans, and all such data, the career must be regarded largely as ing staff. preservation of which to-day is regarded as imperative, were either not properly compiled, or entirely neglected. In my earlier experience in the engineering department of a prominent railway, I was charged with the duty of a complete reof a liue which had been newly scyulred, and in the archives of which not a scrap of paper covoring surveys or roffles or rights of way could be found in the progress of rallway development,

there has been a gradual evolution. To day, it may be said there are two general classifications of railroad engineers; engineers of construction and engineers of maintenance. In some instances the ongineers of construction are still wanderers over the face of the earth. They are the explorers; they carry the banner of civilizatleu into remote corners, and upon their judgment and skill as engineers, as well as upon their executive capacity as ministrators, hinges largely the future efficlency of the routes they open to com merce. In other cases engineers of con struction are staff officers of large systems of railways, engaged in directing the opening of branch lines or the improvement of existing lines, or in other insta юч, directlng new "Construction" spart from what known as "Maintenance

Engineers of maintenance are usually charged with the duty of conserving the property, which involves a knowledge of track maintenance, and of bridges and structures of all kinds, water service, drainage, signals, and interlocking, and of the multifarious details entering into such subdivision of the work

The young man contemplating entering the broad field of engineering as a life's and a determination to pursue with fixed purpose, some one of the several paths along which his predecessors have built ne the landmarks of engineering progress

In dealing abstractly with the two general subdivisions indicated, construction eering and mainten it should be understood that they rest upon the same foundation, or start from the same roots, and the difference in practice is largely a matter of convenier ninistratiou

The engineer of construction on orig railroad location, does have a differ ent view from the man who follows him later as a maintenance engineer, in that he creates the property, and the latter conserves it. Both men have started with same initial equipment as to technical training, and should have the same incentives; loyalty to the profession, desire for advancement and carnestness of purpose The diversion of paths is very often a matter of opportunity, to be retraced or pursued as the personal talent of the young engineer fits into the solution of the problem ahead. How often it has been

A RAILROAD engineer, as commonly said out "at the front" in discussing community and authorstood, in the earlier listory of particular construction, was primarily the man who spied out the land and determined the location of the line. He was a misued the location of the line. He was a material spittude for judging distance, wanderer over the face of the earth. His result of the spied of the spied of the spied of the spied of the spiedure of t

cracting position on maintenance.

The young man, entering upon the career of a railroad engineer, will ordinarily conclude, after a year or two, that the procession up ahead moves quite slow-ly. The first eight or ten years of his preparatory; he is putting some of his technical knowledge into play more or less of the time, and eventually he learns to differentiate between the application of "pure science" to his everyday problem and the application of principles based on the experience of the profession.

Italirond engineering as practised to-day, calls for the highest form of intelligent interpretation of the scientific meth ed as applied to the most practical of

every day problem ere has been thrust upon the railroad eugineers in recent years a grave respon sibility for the safe operation of railways. The public, through legislative action, has demanded almost revolutionary practice demanded aimost revolutionary practices along certain lines Rail manufacture, sigual installation, electrical operation are all special problems, calling for the highest type of technical knowledge. Specialization along such lines is inevitable and the young engineer has a constantly widening field from which to choose.

The railroad engineer is not nece limited in his advancement in railroad service, to progress along strictly engi-neering lines. On many roads the opportunity to take up the so-called transpor-tation problems is not denied him, and many of the railroad officers of important railways were trained as engineers, and as time goes on, there will undoubtedly be an increasing tendency to give such men an equal chance with the man whose men an equaticisatic wint too man works sole training has been along so-called practical lines, but the young engineer who would supire to advancement in transportation work, must not (as was concisely put by a railroad president now self an engineer) remain s work, should have a predilection for the mathematical and mechanical sciences a poor administrative officer. This last a poor administrative officer. This last suggestion emphasizes the need of differ-entiation in the mind of the young engientiation in the mind of the young engi-neer, between the value to him of exact thinking which comes from the study of the engineering sciences, and the ordinary training received outside of the engineerols. Pure mathematics n assist him in systematizing the admi trative features of a large construction corps, but it does aid in prompt and same determination of many of the every-day so-called purely practical problems.

Not all the able engineers were trained in technical schools, but they had to ac-quire and apply the principles of engiquire and apply the principles of each neering science by observation and by con-tact along the slow and oft-times tortuous road we call "experience," so the young man who chooses the field of failroad en-gineering for his life's work, must get his foundation of the sciences som ms rouncetton or the sciences somehow or somewhere, and then pertently and pernistently build up his store house of expertence. There are many paths in the field before him; opportunity lies slong them all. Let him he ready to seeins \$1.

(Concluded from page 258.)

tion to that of the first coil. The wire should be then scraped clean with a sharp knife and the connection made, soldered and taped. Another separator and sec-tion should be placed on the leg and the pected to the outside turn of that one In this manner the twenty secondary units should be assembled, particular care being should be assembled, particular care being observed that the turns of each section run in the opposite direction to those of the one preceding it. (See Fig. 6.) The transformer will produce no spark whatsoever if a mistake is made in the connection. Heated parafin should be poure over the completed secondary until all the spaces between sections are completely filled. This materially increases its elec-

The end pieces of the core between primary and secondary may be next inserted and the completed transformer will appear as in Fig. 5. It may be mounted in a case or immersed in boiled linseed of at the option of the builder. If it is oil immersed (in a metal tank) a space of two inches should be left between the windings and the metal sides. With the suitable condensers and average condi-tions this transformer will transmit sig-nals a distance of 100 miles overland and, at night and over salt water; 200 or n per cent farther.

As the condenser is, next to the trans-former, the most important feature of the transmitter and, in the same relation the most difficult to construct, a few words

here concerning it will not be amiss.

There are two distinct types of condenser in use nowadays in wireless tele-graph transmission; the leyden jar and the glass plate type. Each has its advan-tages. The latter is more compact and corona loss is extremely low. The former, if electroplated, within and without, is ju as efficient and a puncture is m located. The leyden jar coated with tin foil is about the poorest though most frequent selection of amateurs for a condens Tin foil blisters and deteriorates under the action of corona or "brush," breakdown is common and the construction is tedious.

The most effective condenser for an teur use and one that has been adopted in a modified form extensively commer-cially, is the homitest. It has but one disadvantage—bulk. It is practically im-mune from breakdown and corona is entrely eliminated. It is constructed of milk or beer bottles, certainly an appeal to the purse. For the transformer described herein a condenser as construct scribed herein a condenser as construc-ed after the specifications given below will be found much more efficient than one of the glass plate type and breakdown or puncture liability is extremely low. The cost will not exceed one dollar.

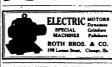

In a metal tub place sixteen quart milk or beer bottles and at a corresponding level fill them and the tub to within three inches of their tops with a saturated solution of sait and water Make the connec tion in the bottles by a colled copper wire and lead them all to a central conductor. The metal tub will constitute the connecnaturally, adapts itself to the irregulari-ties of the glass surface, hence no air bubbles to invite breakdown will form, pubbles to invite breakdown will form, and the surface dissipation leakage can be entirely eliminated by pouring on boiled linseed oil until a layer 1/4 inch deep is formed over the water.

In conjunction with the 1 kilowatt transformer and condensers, to comply with the new "Wireless Law," a helix of the loss-coupled type must be employed to insure the radiation of a wave free from unnecessary damping. This may to insure the radiation of a wave free from unnecessary damping. This may consist of a wooden frame, say 14 inches in diameter and 10 inches high, wound with heavy copper wire, as in the case of the old-style bulk, but in which a small-er, consentric coil of a fixed number of wints of finer wire, is made to side and four wary the coupling. By A. RUSSELL BOND Author of "Scientific American Boy," "Scientific American Boy," "Scientific American Boy," and "Handy Man's Workshop and Laboratory.

6x834-275 pages-101 illustrations, including 59 page plates-one in color

A BOOK of engineering for boys, telling in a boy's own way what every boy wants to know. It recounts the expenence of two young lads who spend a summer vacation seeing the engineering wonders of New York. The boy with red blood in his vens will be thrilled by the numerous adventures, all based on fact, showing courage, presence of mind, loyalty comrades and devotion to duty; at the same time he will learn how the big things of engineering are being done. A docen engineers, experts in their everal lines, have read and revised the manuscript.

### Direct Name Systèm of Vertical Filing

"Leaders of the World" in Filing Systems and Business Equipment

### The Proof of Filing is Finding

In the "Y and E" direct Name System filing errors are prevented—therefore there are no finding troubles.

This System possesses five important advantages: (1) Speed in finding; (2) Speed in filing; (3) Assured accuracy of both; (4) Economy of cost and maintenance; and (5) Quick transferring.

renance; and (3) Quick transferring.

The guides are of pressboard with celluloid tabs and will last 50 times as long as manila. They are printed with alphabetical subdivisions and numbers. They can be used year after year for the guides are not transferred but are left in the active file, as the tabs of the folders serve as the index in the transfer case.

Send for sample folder and free book, "Vertical Filing Down-to-Date"

Its 40 pages fully illustrate and describe the "Y and E" System. Write for a copy on your business letterhead.

tained from the nearest Government radio aspector for erecting a station of this nature before its construction is seriously ontemplated as the federal law prohibits the operating of unliceosed apparatus

### Ocean-going Submarines (Concluded from page 284.) tion of their numbers; and in a general

world. In the mere fact of this reticent is to be found convincing evidence great importance which is attached to tid ranch of warfare. Decided and helittled in the early days

of its struggle for recognition, the subme rine at last has come into its own. The principal objections against this type during the early years of experimental work were its lack of speed, its limited steaming power and its restricted radius of action. So great were these limitation that it was considered to be useful merely bor defenses in the way of long range guns, mortars and submarine mines. That the charge was well founded is proved in we call to mind the limited dimension and power of our submarings at the com mencement of the present decade. The bonts of the "Adder" class, of the year 1902, were only 63 feet 4 inches in length of 120 tons displacement, and of seven to eight knots speed. They carried but one torpedo tube and a very limited supply of gasoline. Four years later the submarine of our navy were still very small craft their length being 80 feet 6 inches, then displacement 170 tons, and the speed 10 uspacement 170 tons, and the speed IC knots on the surface and 8½ submerged. To this class belong the "Curtletish," "Viper" and "Tarantula" of 1906

Between that date and 1009, when the

boats of the "Stingray" class were launched, there was a marked develop ment, the displacement increasing to 274 ment, the displacement increasing to 27stons, and the horse-power for surface pro-pulsion to 500, as against a surface horse power of 100 in the "Adder" of 1892. The armament was doubled, these vessels carrying two torpedo tub

it was now realized that the submarius was so far developed in efficiency that the time had come to enlarge its size the time and come control of the habitability, crubbing radius, sufficiently to enable il to become sea-going, al least to a limited extent. Hence, we find that the loats, of 1911 have an overal length of 148 feet, a displacement of 520 tous, that they can develop 950 horse power when steaming at the surface, at nower when steaming at the surface, at a maximum speed of 14.5 knots, said that in the submerged condition they have a speed of 10.5 knots. Furthermore, they can travel on the surface for 2,500 miles at a speed of 11 knots, which means that at a slower speed than this and with a full supply of fuel in their tunks at startiug, they are capable of steaming acros the Atlantic Ocean.

We present an illustration of one of the latest submarines, completed for our nay, in the Fore River yards, Quincy, Mas She is one of what is known as the K class of eight boats. Her dimensions are Length, 148 feet; diameter, 15 feet. He radius of action at the surface is 2.500 radius of action at the surface is 2,000 miles at 11 knots, and she can travel 120 miles submerged at a speed of five knots. Our latest designs carry four torpedo tubes and have a cruising radius of 4,500 miles.

That the submarine will ultimately in

ase in size, habitability and speed unti it is perfectly well able to accompany the it is perfectly well able to accompany the battleship at any desired speed on the high seas, is abown by the dimensions which have been cabled from abroad regarding the intest Buttish submarine, which is knots and a surface speed of 35 knots and a surface speed of 36 knots among the various lines along which have always and the surface of the surface of the surface Among the various lines along which have interest is being registly developed, we know of none that presents such pos-sibilities or is full of greeter promise than this of submarine warfare.

### The Chronology of Aviation

THE Scientific American has received from Mr. Hudson Maxim and Mr. William J. Hammer, a limited number of the repunts which they have just issued of the very complete "Chronology of Aviation," originally prepared by these gentlemen for the World Almana of 1911. The data embrace the essential facts relating to serial progress. In addition to a short historical refundit, one finds herein tables giving allitude records, speed records, queck stating and slow-speed records, pastenger carrying. English Channel and other over-water flights, cross-country flights, notable distance and duration flights, etc. There are also statistics relating to accidents and data relative to spherical and drugble balloons or arrishing, etc. Of no small interest are the tables giving the most important flights of the Wright brothers. There are doubtless many readers of the Scientific American who are much interested in this subject and two would be glad to secure a copy of this interesting brocknire. They can do so by applying to the Aeronautic Editor of the SCIENTIFIC AMERICAN, 361 BROADWAY, NEW YORK SCIENTIFIC AMERICAN, 361 BROADWAY, NEW YORK

### Let Emerson Train You

IT IS now possible for you to be trained at your home by Harrington Emerson, the best known of all Efficiency Experts.

You can get by mail the same training that you would get in Mr. Emerson's offices, where he supervises the work of forty highly skilled specialists.

The whole story of the Emerson Method of Effi-ciency has been condensed into 24 Lessons, so that you can acquire an Efficiency Education without leaving your home or giving up your present occu-pation.

### Emerson Institute of Efficiency

Harrington Emerson is the man who first made Efficiency famous. It was he who SHOWED the railroads HOW they could save a million dollars a day.

He is the most highly paid of all Efficiency Ex-perts, and is consequently the best fitted to train others. As the head of the new EMERSON INSTITUTE OF EFFICIENCY, he will per-sonally supervise the whole rourse of instruction.

### \$2,000 a Month

In the last twenty years, Mr Emerson has trained scores of men. Every one of these men is now drawing a high salary. One of them is receiving \$2,000 a month.

Every great corporation is demanding men who un-derstand the principles of Efficiency.

derstand the punciples of Efficiency.
There are more BIG [JORS than BIG MEN. Never below has there been such an opportunity for a man who is ambitused and personal control of the state of the properties of the properties. The properties of the pr

ROBERT D. CHASE, Secret

30 Irving Place New York City

### The Ruler of a Kingdom

The man who sits at the steering wheel of his New Chalmers "Six," rules an empire. Here within reach of his arm is a little world all his own. Power, speed, endurance—the forces that make for change and enjoyment—are under the sway of his scepter.

At the touch of his finger the might of sixty horses—eager but restrained—stands ready to do his bidding.

### Let's Take a Day Off

Don't you feel like cutting the traces, and getting away to the hills? Let's strike out—what do you say?

strike out—what do you say?

Push the switch of the electric starter. There—the engine is running with scarcely a sound. Now the starter has reversed and is recharging the batteries ready for the next time. The silent Entz system does all this automatically. You don't have to give it a thought.

### Floating Away Like a Swan

Close your eyes now as we let in the Close you can tell when we start. This new clutch is a wonder. Its steel discs with their many fingers of cork, grip so firmly, yet so gently, that we move away with the silent grace of the swan.

We're off. Notice how flexible the power—mounting quickly to 20—30—40 or even 50 miles an hour. Now we throttle it down to two, without shifting gears—then away again swift and silent as the eagle's flight.

This wondrous flexibility is in the motor itself. There's no need to resort to cumbersome double gearing.

### The Mystery of its Silence

Listen as we speed her up a bit. You hear nothing but the rush of the wind. We have discarded the noisy little wedge-like cams still generally used. Our big, oval cams lift the valves and

slide them shut with velvety smoothness. So here we are spinning along at fifty miles an hour as quietly as at fifteen. This silence tells you that there is no friction, no wear; that year after year this car will keep on running as quietly and smoothly as it runs today. When you can have such a car, why be content with any other?

### An Immense Saving for You

Let's take a look at the motor. A beauty, isn't it? Not a moving past in sight.

The valves are made of Tungsten steel so hard you can cut glass with it. The terrific heat of the cylinders never injures them.

So they never leak nor waste power.

They rarely need regrinding.
Tungsten steel valves cost us \$80,000
extra per year but they mean an enormous saving to you.

### Easy Chair Comfort

Have you noticed that in this car you don't feel the vibration you do in most cars? It runs with a smoothness impossible in any four-cylinder car and very rare among sixes.

Vibration is the chief enemy of durability. The absence of it nearly doubles the life of a car. It doubles the comfort too. You can ride all day long in the New "Six." with the comfort of your easy chair.

### A Little Friend in Need

Watch now as I cut down the power until we barely creep along. I am not giving the motor enough gas for the work it is doing. Any motor would ordinarily stall with so little gas. But now I push out the clutch to change gears.

At once, this wonderful motor picks up. The Chalmers-Entz Electric starter does it. It keeps the motor running—won't let it stop. Think what that means in crowded traffic.

### Mounting Like Eagles

Now up we go—taking the long mountain grades as easily and quietly as the level stretches. The absence of effort is amazing.

### Chalmers Motor Company. Detroit. Mich.

The power of this master motor seems limitless. Its valves are bigger and open wider than common; they can't obstruct the flow of the gases. All six cylinders draw gas equally from a triple-heated reservoir. So even with low grades of gasoline, every atom is turned into power. Think of the saving in a season's fuel bills.

### On Top of the World

Two hours away and here's a new world spread at your feet. Let us take a look at the car that made it possible.

Look at the graceful lines of the bell-shaped body—roomy and comfortable. See the graceful, molded oval fenders.

Tires are carried in the rear, leaving the running board clear. Gas tank in the rear too. It holds 22 gallons.

Of course, you've noticed that the driver sits on the left. Control levers are in the center, leaving plenty of room to enter from either side.

### A Home Run

Luncheon over—and we're off again for home. See how gently our big brakes ease us down the steep grades; how our long underslung springs and drep upholstery cradle us over the bumps. See the landscape flying backward like a scudding cloud.

Surely in all the world there's no car like this. It gives a luxury of motion you've never dreamed of; a world of enjoyment in motoring you have never known.

### Put This Car To the Test

Go ride in the New "Six." Let our dealer take you out on our Standard Road Test. It is our way of proving to you that this car will do things that no other car will do.

PRICE 10 CENTS

### Cutting Down the Pitisburgh "Hump" District

By Harry Chapin Plummer

There is rapidly approaching completion in Pittsburgh what is known as the \$5,000,000 "Homproment. In tess than two years the grades of streets aggregating 2.16 miles in length, forming an area of 33 acres, which had long been known as the "Hump," have been reduced by a maximum cut of 103. feet. The physical undertaking alone, acclusive of the outlay following condemnation proceedings, has cost \$800,000.

The work has been of benedit principally to Fifth Avenue, one of the city's chief arteries of business traffic, and the work has centered about the handsome Allegheny County Court House, one of the

Alleshary County Court House, one of the finest public buildings in the country, the Frick and Carnegle office buildings, both "akyserapera," and the County Jail. Frior to the commencement of cutting operations, Fifth Avenue had a grade of 7½ per cent, which rendered the thoroughfare actually daugerous for raffic, at times when the pavenents were well with rish, or were fee-coated in the winter. Moreover, the narrowness of the street combined with the steep grade to cause an aimost constant congestion.

To effect the useded improvement, it was mecessary to cut away the creet of the "Rium," and by this change the ground floors of the massive buildings fronting upon Firth Avenue became the second floors and the basemonts became the street floors. This necessitated sweeping attentions, not only in the very structure of each of the buildings, but in the catrances and loblies and elevator facilities. The lower portion of the fanded or each of the office buildings has been practically remodeled

As the result of these improvements, the grade has been reduced from 7.5 to 48 per cent. The improvement in the grade and the architectural treatment of the lower portion of the buildings is strikingly shown in the accompaning illustrations.

### If Anta Were as Big as Men

S PENCER in his "frinciples of Hology".

Shas shown that the power of assimilation in animals is dependent on the surface of the digestire duct, and that it varies as the square of the dimensions of the body, whereas the consumption of material is proportional to the cube of the same dimensions, so that the ratio of the two factors decreases at the same rate as the size of the animal lucroses.

the size of the animal increases.

This principle, as pointed out in the Recue Retentifyace by Dr. Ywes Delage, is of the lighest importance it understanding indogeni phenomens and lead-to a number of interesting conclusions only partly enunciated by Spencer.

It has frequently been suggested that the ant is relatively stronger than either man or horse. The insect can earpy on its frail legs a grain of corn ten tinese the weight of its body, whereas man and horse carry leads equivalent only to the weights of the tody, whereas man and horse carry leads equivalent only to the weights of their bodies. The inference that the ant is greatly superior from the point of view of its structure and strength, can be shown to be strongent and strength, can be shown to be strongen and at to grow in all directions to twice its origing dismensions, but will retaining its geometrical and histological structure. Its volume and accordingly the weight of its body will increase eight-fold. The suschess there is no the strength of the strength.

Canal Brokenson - 10

which is only proportional to their cross-section, the ant increased to eight times its weight is only four times as strong as before, that is, carries only forty times its original or five times its present weight; in fact, it is in proportion only half as strong as before. If now the same ant grew in all directions to dimentions, not two but a thousand times their original figure, thus reaching the size of a man or horse, it would be a thousand times weaker than before, being able only to carry 1700, instead of fen times, its own

I believe terms the ratio of the power of assimilation to the consumption of the body its "physiological efficiency," and accordingly emmelates the theorem that this factor decreases at the same rate as the size of the body augments. This theorem applies

The work of cutting through a street, house and store so as to lower the grade of Pittsburgh's Fifth Avenue from 7.5 to 4.8 per cent.

Cut of 14.9 feet, whereby the first floor, occupied by a savings bank, becomes the second and the institution must remove to the new street floor.

Fifth Avenue in the "Hump" district after the completion of cutting away the

to physiology as well as to outogen and phylogeny 1. Physiology. Since pencifically all organs producing substance useful for the organism, as well as those serving to eliminate waste materials, are hollow organs depending for their working capacities on their surface, while the consumption of those substances and the production of waste materials depend on the volume. Speacer's proposition, as medified by Delage, will be resultly understood

2. Ontograp The morphogenous phenomena of oncogeny consist multily of invaduations and protrusions by which the organism with lis complicated forms and internal organs is produced from the round e.g. When the development of the embryo has come to an end, the organism has reached its maximum physiological efficiency, which accounts for the fact that his growth is

then the most rapid. As the growth of the organism continues, the physiological efficiency, however, decreases, and when the productive powers just binaince the consumption of the body, growth comes to an end under normal conditions. The equilibrium thus stended will last for a long time. Any deteloration of the body try disease, etc.), however, reduces the power of usefullation, whereas its cuisumption remains practically unaffered, that is to say, the physiological efficiency of the body decreases, and this continual decrease eventually results in the death of the built should.

3 Phylogeny When considering the evolution of various phylecte pedigrose, a striking parallelism is noted between the physiological efficiency and the outogen-sels of individuals. In fact, each such pedigree commences with samil, slightly differentiated forms, in noder by gradual evolution at hash to arrive at highly differentiated forms of considerable dimensions, which eventually vanish, time extinguishing the whole pedigree. Since the physiological efficiency of large sized animals is very low, the utilimate extinction of these speckes will be resultly known.

Houbitiess there are other factors as well at play in connection with these phmomena, but the "physhological efficience" of Individuals and species may certainly claim a paramount position as a determining factor.

#### Fine Specimen of Mammoth Found in Siberia

THE Natural History Museum of Paris Theorems of the specimen of man moth with the flosh paris preserved to a certain extent. The specimen was offered to the museum by the Count of Slenhock-Fermor who found it in one of the Islands of the Siberdan region. After extracting it at his own expense be brought it to Europe by sled, boat and rullroad. This be probably the only specimen of the kind which central Europe Is to possess, for the Russian government has besued a takes probably the only specimen of the kind which central Europe Is to possess, for the Russian government has besued a takes probably the only specimen of the kind with the or in part. Such animals preserved in the lee have been known state 1806, but the only specimen preserved under these conditions up to the present and brought to Europe Is to be found at the museum of the Academy of Sciences at St. Petershare.

Lately, the Russian selectists have been engaged in studying the flexiby parts from the standpoint of anatomy, histology and the Bike, and these researches are expected to gledd some valuable data. As to the Parks specimen, it is well enough preserved to allow of carrying on similar researches, and these are already in propagation of the property of the meaning the property of the property of the meaning of the mea

simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

#### A Dangerous Bill

a matter of international courte A right for Representative Kalm of California to introduce in the House a bilt which will enable withblors at the Panamu-Pacille Exposition to import free of duty articles and building materials intended for the Exposition But does international courtesy denound that the Librarian of Congress and the Conper of Putents he required to record "any certificate of registration, convright, trade mark, or natent the foreign exhibits at the Exposition?

Clearly, the management of the control o

Clearty, the purpose of the mensure is not only to permit foreigners to escape our duties, but also lo prevent the citizens of this country from manufactur-ing, using and selling imported articles of merchandise not patented in this country, but exhibited at the Ex-position. As the bill is now phrased, it matters not not provided as the bill is now phrused, it matters not that the foreign exhibitor never applied for a putent in this country. Indeed, the bill would give him provided in this country. under our copyright, trade mark or patent laws there ever a measure more clearly unconstitutional?

Our putent laws are open to citizens of foreign cour We grant patents to foreigners on exactly the same terms us we grant them to the eltizens of our own country. If any biventor fulls to take advantage of the putent lows the public may appropriate his inven-tion. A law which seeks to afford protection to foreign exhibitors at San Francisco he violation of the consti tution and our own patent laws would be class legis-lation and an infringement of the rights of the citizens of this country to use unpatented articles freely
lills such as this testify to the urgent need of some

advisory body which will point out the flaws of well-menut, but foolish legislation, and which will avoid hours of ascless delate in Congress. The patent laws are particularly sching marks for Ill-Informed Con-gressmen Hutdly a year passes but some absurd bitts are introduced which seek to curtail the very ed privileges that inventors now enjoy-bills which named privings and investors now enjoy—bills which are framed by legislators who have not the slightest realization of the part played by patented inventions in the un-building of this country, and which a well-infrarmed abeloxy board would promptly relegate to the limbs of bad dreams

### "Dual Personality" in Court

AS by Jekyll legally responsible for the crimes of Mr Hyde? This question was recently declared in the affirmative by an English Juny, but the precedent established seems rotten to point to a defect in the law than to insure justice in the settlement of such cases in the future. The case in question was notable for the scientific evidence addition to behalf of the accused.

A young engineer named George Chetwynd, of good scial standing, was charged with the theft of a motorcar belonging to one of his friends, a Doctor Barron. The necessed was alleged to have broken into the doctor's garage, removed the car, atteced its number, and us he had no money, secured some gasoline on credit before making off with the machine. A curious feature of the affair was that the accused knew where the key of the shed was kept and also where the doctor kept his supply of gasoline, but did not avail himself of this knowledge After being arrested and lodged in jail, the prisoner, appeared to come out of a trans

and professed to have no recollection of what he had

The owner of the car seems to have been willing to drop proceedings, but the public prosecutor insisted on a trial. Counsel for the defense admitted that his client had committed the theft, but deciared that, when doing so, he had been in a condition known to medical men as "automatism."

I'r Parry Jones, of Derby, stated his belief that the

It learny Jones, of herby, stated his belief that the case was one of automatism, and that the accused was not morally responsible for his actions. He cited a number of similar cases from medical records. The weightlest evidence, however, was that of Dr.

Hyslop, one of the highest English authoriti all diseases. He pronounced the condition of the ac-cused to be one of mental automatism, which was nildway between somnainlism and a minor form of collision. In such a condition a person may perform complicated mental and physical actions, yet have no recollection of them on recovery. Unfortunately for the accused, Dr. Hysion declined to qualify the case as one of insunity, and this technical distinction, coupled with the inelasticity of the laws, probably left the jury no alternative but to decide as they did. The same expert raised a curious question in ethics by stating, on cross-examination, that (to quote the report of the case in the *Times*) "there were cases of mental automatism in which the abuormal irres sible self knew at the time what it was doing, but the normal self would have no recollection of it" in other words, self A knowingly breaks the iaw, but before the case comes to trial has ceased to exist, and is replaced by seif B, which has no knowledge of the crime—in fact, did not commit it. How is justice to be done in such a case?

lu his charge to the jury the judge took an easy

way out of the difficulty by adopting a skeptical atti-tude toward the mental phenomenan in question. The jury found the accused guilty, and he was sentenced to four months in jail,

Of course, the outstanding fact is that, regardless of the merits of this particular case, the phenomenon of dual personality does sometimes occur, and may lead to a situation analogous to that of Jekyil and If Hyde knowingly does wrong shall Jekyli be published? Probably if such cases were more common the law would provide for some form of restraint, as in cases of insanity, but would not inflict the opprobrium of a juli sentence upon the unfortunate possessor of a dual personality only one of whose "egos" was addicted to crime

### Painting the Town With Phosphorescent Paint

VERY clear day there is poured upon walls and buildings an immense amount of solar energy, causing in many instances such a glare of brightness that men adopt various scre studies to relieve the strain mon the sensitive nerves stacies to renew the strain upon the senior between con-of vision. The only attempt that appears to be made to utilize these surfaces seems to be the requirement, in certain large cities, that the rear and inner walls of buildings shall be painted white, in order to check the absorption of light, and relieve the darkness of inner orts and ventlitting simfts. Every day this brilliant display of solar energy is allowed to be absorbed, reflected, dissipated, while upon every succeeding night there is expended a costly effort, in power-houses, gusworks, and off-combustion, to produce such feeble ef-forts at illumination as will render possible the pro-

ioris at mumination as will render possible the pro-longation of activity for a few hours. In view of the results which have been attained in the efforts to utilize storage methods for the electric current, it seems most desirable that some similar system for retaining at least a portion of this illuminatsonshine may become practicable

It is well known that there are a number of subes which possess the so-called power of "insola" that is, the capacity of being so influenced by the action of the rays of the sun as to emit a cerdegree of luminosity. Although the substances which have been most generally employed for the demonstra-tion of this peculiar property are numerous, the power is possessed by them in a rather feeble degree, and the best of them costs considerably more than would permit its general employment. It seems possible, how-ever, that the property of emitting tight for a consid-erable period of time after exposure to brilliant suneraine perion or time after exposure to brilliant sui-light, as possessed by the sulphides of calcium or stron-tium, for example, might to developed to a far higher degree if the subject were investigated with the same care and skill as have been given to the examination of materials for the manufacture of incandescent gas mantles, for instance it seems probable that a thormanties, for instance it seems probable that a thor-ough and vigorous study of the subject of phosphor-escence, and the development of new compounds for the increase of the property of insolation, would place the matter upon a commercial basis to an extent comparable with other methods of deriving artificial illu-

The method of employing such phosphorescent mate

rials would be so greatly simplified over existing systems of lighting, as to demand interested attention. All lath would be necessary would be to prepare the material as a point and spread it upon the surfaces of buildings, especially those exposed to brilliant sunlight during the day, in order to enable the same surfaces to return the stored sunlight during the night, and thus provide an automatic equalization of the light energy of the sun. The principal cost of such a method would be that involved in the preparation of the luminous paint, and in the maintenance of the clean surfac ce the operation of absorption and emission of the light would require no further attention, all mechanical devices being conspicuous by their absence. The general use of such a paint would enable the more powerful methods of artificial illumination to be limited to special iocutions, and confine the use of existing sysis to indoor service and points to which so daylight penetrated as to provide insufficient insolating action upon the phosphorescent material. Such a method as indicated seems to offer possibilities as great as any effort to discover the manner of producing the feeble cold light of the glow worm, or the firefly, and since it offers a plan for the direct utilization of one of the elements of the radiant energy of the sun which has hitherto remained uncontrolled, it appears to be well worthy of serious study. With the equipment of existing chemical and physical inhoratories, it should be possible to press our knowledge of the phenomena of phosphorescence and fluorescence to a point far beyond that now obtaining, and the reward of a successful solution of the problem would be so great in itself us to render unnecessary the provision of any other prize to the successful investigator.

### The Direction of Aerial Highways

MONG the eastern tales which M. Antoine Galland brought from Constantinople about two A land brought from Constantinople about two A himdred years ago, there was one about a mountain of indestone, which destroyed ships by attracting and drawing out all the iron nails. This was before the days of manufactured electricity and of electromagnets, and no one knew of the existence of magnetic waves which night be used to transmit signals, and help vessels instead of injuring them, but it did include the memory of the contraction of the contrac the germ of a truth which has only begun to be uppreclaied, and even as yet but little utilized. the influence of magnetism supplies not only the mag-netic needle, by which a guide for direction is provided, but il also mables shore stations to send out time sig nals, checking the chronometer, and insuring correcterminations of longitude.

It is possible that there may yet be developed such a control of magnetic lines of force as will enable air routes to be directed in a manner even more definite than the lanes in which transatlantic steamers are oper-

One of the greatest difficulties which appears in the way of long-distance aerial fourneys, assuming the practicability of continuous flight, is that of maintaining the desired direction, in the midst of clouds and fog, and in the darkness of the night. The vibration of the machine, and the difficulty of taking observations of position, even in clear weather, render it most desirable that some positive and direct guidance be furnished, not limiting the machine to such a close line as to involve possible collision with others, but indicating defaultely the route along which progress should be

Hertz has indicated the practicability of directing magnetic waves, and Tesia has proposed definite trains of electrical waves, and it seems as if further work and it seems as it turner were along these lines might result in the development of a method of indicating sir routes, independently of any observations of the compass or of celestial bodies. The existence of a definite train of waves through space, say from New York to London, which would immediately the contract of ately indicate to the airman the fact that he was in the right road, probably by the response of a sensi-tive detector, would permit him to dispense with any other effort lo direct his machine except to keep it within the path of magnetic effect, and to watch for any material deviation from the path. Such a method any material deviation from the jeth. Such a method would be wholly apart from any attempt to transmit energy by means of waves; that is, sufficient energy to be capable of use as projetiling power, but it would enable the response of the detector to assure the navigator that he was proceeding in the direct path to bis destination, in whichever direction he might be breaked.

It is not improbable that the successful intro ch directive regions would later lead to the supply of motive power through space and thus remove one of the chief practical difficulties to long-distance aerial travel, the limitations of fuel supply. Each development in such work leads on to the next, and the surest way to attain such a result as a stream of directed radiant energy over a determined route would seem to be the provision, at first, of a guiding line, which might later become something more.

#### Engineering

Turbins Casings Purchased Abread.—By purchasing the turbine easings for the battleship "New York," now building at the New York navy yard, from Cammel, Laird & Co., the Navy Department will save \$102,000 on the cost of these easings, had they been purchased of the lowest American bidder.

The Busiest Rallread Terminal.—Although the Grand Central Station, New York, is the largest, it is not the busiest terminal in America. Statistics for the year ending June 30th, 1913, showed the total number of pasengers in and out of the Grand Central Terminal was 22,403,295, whereas for the same year the total for the South Station at Boston was 38,411,507. Of this total, 28,347,399 represented pasengers of the New York, New Haven and Hartfurd Rallroad Company's lines, and 10,044,108 were passengers on the Boston and Albary line.

Sixteen-inch Gun to be Mounted.—The experimental 16 inch, one-defense gun, which was built a dozen years ago at the Watervilled Armeni, is no longer a "white elephant" at the Sandy Hook Proving Ground, to which it was sent for test. The gun stood lis train satisfactorily; but because big guns such as this went out of favor and were displaced by high-velocity, 12-inch guns, the big piece has lain for a decade at Sandy Hook. A disappearing gun carriage, however, is now being hult to carry the piece, and it will form part of the hattery of the defenses of the Panana Carlo.

The Safety of Steel Trains.—In a letter to the Now York Yimes, the well-known signalman, James O. Fagan, endeavore to make out a case against the steel of the structure than the vocal on the ground that, because of its greater weight, it is more destructive to roadbods, bridges and general structures than the wooden care. But it is not the weight of the car but the weight of the very heavy engue that controls this question. Bridges and tracks have been or should be attempthened to accommodate the great increase in engine weight, which has been so large as to render the increase in the weight of steel care over wooden care of minor importance.

"Safety First" Time Tables.—There has been a revision of the time tables of the New Haven Railroad the guiding principle of which was consideration of the safety of the passengers. The read operates about 2000 brains every day in the week, and of these some two thirds are affected, notably the through trains and long distance local trains. The running time of the New York to Boston through trains has been lacreased by from 5 to 20 minutes. When the road bed, rolling storated and grad system have all been brought up to about the first date condition it will be time to return

Demand for Tractors.—At the present time there is a good domand for automobile tractors in English South Africa, the principal reason being the epidemics of horse disease (epizootie) which cause a great dimination in the number of horses in this region, so that power wagons are becoming indispensable for carrying on agricultural work. The kind of automobile needed for local use should be of simple and substantial makeup, suitable for use with plows and harrows, and for hauling material. Efforts are being made of iate by the agricultural associations in order to promote the use of power wagons, and especially of tractors combined with plows.

Largest Marias Diesel Engine.—The recont arrival of the ship 'Wothan' in New York Harbor, is of interest because the ship is propelled by a single-serow, six-cylinder, two thousand horse-power Cardis-Diesel marine engine. Other motor ships that have come to this port, we gross capacity was about 2,000 iff. Pr and in each case they were supplied with injection air by additional engines. The motor of the 'Wothan' is a six-cylinder cogine with an injection air compressor on the engine. This is the largest marino Diesel engine in service, and the good record of the ship on her maiden voyage is another proof of the reliability of this type of drive.

Two Additional East Biver Tunnels.—It is only as the wysers alone the construction of a subway tunnel below the East River excited wide-spread futerest because of the difficulty and magnitude of the understaing; but to-day we have got into the way of building tunnels under that river almost as though they were common-place forms of engineering work. Two new tunnels are to be built in connection with the dual subway. The Interborough tunnel leaves Manhattan at Old Stip and runs under the East River to Clark Street, Brooklyn; the other tunnel to be built by the New York Mundepal Corporation will extend from Manhattan at Whitchall Street below the East River to Montague Street, Brooklyn; the other tunnel to be built by the New York Mundepal Corporation will extend from Manhattan at Whitchall Street below the East River to Montague Street, Brooklyn; the other tunnel and Long Island will be joined by twelve separate tube tunnels and by four of the greatest bridges of the world, through and over which will be about 50 separate lines of tracks.

### Electricity

Deable Telegraphone Becords—Prof. Pedersen is taking up the Poulsen telegraphone or magnetic phonograph idea and now perfects it so that creellent results are to be had. He runs a steel were between a pair of hobbins, and upon the wire are placed electromagnets nearly touching it, as usual, so that when he peaks into a steephone connected with the magnets, this gives a magnetic record upon the wire as it passes along, but here he uses two separate magnets spaced on the wire, and finds he can thus record two separates conversations on the same wire. On reversing the wire, each conversations on the beard in its awn telephone.

Stopping Trains Electrically.—Experiments have recently been made on the Havrana State Railways with a method of stopping railway trains electrically. The system is referred to as one of wireless telegraph communication between a wire strung on the roof of the baggage car and any telegraph or telephone lines ranking that the train the robably induction is used rather than Hertzian waves to convey the signal to the train. The apparatus operates either a bell or a light signal in the call of the locomotive or it will operate directly on the art brakes. The system calls for the lastallation of a sending station at frequent intervals, so that if it he desired to stop a train because of some sociden, this may be effected from almost any point alone the track.

Cadulum Storage Battery Plates.—Pörseks and Ashenback use a new process for making cadulum electrode plates for alkaline accumulators. They use cadulum obtained in finely divided form as a spongy precipitate from a solution of cadmum said. In order to obtain it, they add zine provider to a solution of cadmum shorted with zine powder and a small amount of oxide of meetry, is spread upon suitable supports for making the battery plates. Such porous cadmum electrodes are used in a coastic social or posts hath against a nickel electrode. At the first charging by ourrent, the meetury oxide is reduced to the metallic state and the mercury then envelops the particles of cadmium and zine. On thesagring the battery, the zine dissolves out, while the cadmium becomes oxyclized and the mercury remains in the same state and is not affected. The zine thus remains only temporarily in the mass, and add in rendering to propose.

Lecomotives for the Milan-Varces Railread.—There are now in use five electric hecumotives of quite a new build upon the electric railroad running from Milan to Vareas. This road is 60 miles in length and use a stirid rail with 650 volts direct current. Several substations along the road recove high tension current at 53,000 volts from a power hie, and feed current into the road used motor cars for the trains, and also one electric locomotive, but it recently had the five locomotives to which we refer built by a Milan works. These are of the Brown-bover type and have three driving whoels and two carrying wheels. On the locomotives the works of the seven when the seven had been a set of the seven of the seven had been as the are coupled to a common driving rob bar. The rod is also connected with each of the motors drive the three wheels an an officient manner. The new locomotives serve for freight and manner. The new locomotives serve for freight and spessenger trains and can make 60 milles at notur. The total weight of the locomotive is 72 (long) tons and achieves weight 45 tons.

Exhausting Lamp Bulbs at High Temperature.—A new method is used for making a vacuum in meandescent lamps or other glass vessels. Heretofore, to eliminate the last traces of moisture and exped air hubbles which addrect to the side of the glass, the lamps have been heated in a special furnace lined with aebestos to equalize the heat to a temperature of 250 or 30 deg. Cent. (482 or 692 deg. Fabr.). But all the air bubbles do not detach even at this heat, and a greater least cannot be used for fear of softening the glass, when the air pressure would collapse the bulbs. Quite lately the Berlin Allegemeine Company used a vacuum process which allows of heating to a higher point and to go even up to softening of the glass while the lamps are on the air pumps. This is done by placing the lamps in an olectric furnace in which a vacuum is made, so that there is scarcely any external pressure out he lamps and they can now be heated as high as 500 deg. Cent. (952 deg. Fahr.). Larger end tubes can be used on the isamps which is better for the vacuum process, but it is a hard matter to fuse of such large tubes for closing, when they have a vacuum inside, as collapsing may occur. An original method is used for this, and a spiral wire electric heater surrounds the tube so that it is softened and can be drawn out while still inside the furnace, and the closing off of the lamp thus effected without air pressure on the outside. When this is done, the furnace is allowed to cool down to 350 deg. Cent. before opening and putting on the atmospheric pressure.

#### Science

As Austrian South Polar Expedition, now being organized, is expected to sail from Trieste in May, 1914, under the leadership of Dr. F. Konig, of Graz, in the ship "Deutschland," recently used by Leut Flichner's Alatactic expection. Dr. Konig is a geological and an experienced Alpine climber, and dook part in Flichner's expedition to Spitzbergen in 1916.

Geocentric Altitudes of Mountains.—In our sense MI, Everest is the highest mountain on the globe, but in another sense it is overtopped by at least 25 other peaks. Prof. August von Bohn has eincludated the "geocentric" attitudes of 31 high mountains, a c., the distance of their summast from the center of the card. Chimborazo, in the Andes, stands at the lead of the bet, Everest stands near the bottom, and is, geocentrically, about 1.3 miles lower than its South American rival

A Mining Exposition will be hold in Hortscultural Hall, Philindelphin, the week of Netoker 30, no connection with the Annual American Mining Congress. It will include, among other things, outhiet of noting mechanicy resone and first-aid appearance, and artest appliances several lag coal companies well send resone and first-aid crows, which will give exhibition drills, which the United States Bareau of Minics will be represented by one of its earlier was and a proked crew of helmet men Annung the industrial cellulate it is proposed to have a gold-onlining early in till operation, with a mile envising the continuous and in the continuous continuous and continuous continuous and continuous continuous and continuous cont

The Sanitation of Soda Fountains, "An urgent and apparently neglected question is discussed by Dr. W. S. Rankin in the Bulletin of the North Carolina Bloard of Health. This writer fluids the solution of the problem in the use of paper parafill on upus and sancers. These can be sold at about half a cent apiece. In the process of manufacture they are dupped into metical parafill, and are practically storile, they are put up in stacks, and in using thom at the fountain the attendants do not touch the inside of the cup or the upper third of it. Of course the cup is thrown away after once being used. The spoons used with the cream should be dipped into antiseptic solution before the customer is served.

Water Power Development in the Scottish Highlands are discussed by Mr. A Newlands at the last meeting of the British Association. The possibilities of the Highland region in this direction appear to have beginning arrivingly neglected. Its logid mountain ranges, lochs fed from large drainage areas, a canfull ranging from 30 to 100 inches per anium at high altitudes, steep and rapid rivers, good transportation frechities, and sturdy industrial population seem to mark it out its a favored site for hydrachetric undertakings. A start has been made at Kinlochleven and Foyers, where the British Aliminium Company already generates 30,000 and 7,000 lores power, respectively, and there are a number of smaller installations, but for the most part this field is un-worked.

Wireless Weather Reports for Marlners, usued by the United States Weather Bureau, are now distributed broadcast every coming shortly after 10 o'clock by the Naval radio statems at Radio (Arington), Va., and Key West, Pla. The report consists of two parts, the first gring in a simple figure code the harometric pressure, wind-direction, and wind-force (on the Beaufort seale) provailing at 8 o'clock the same evening at Sydney (N. S.), Nantuckel, Allantic City, Cape Hatteras, Charleston, Key West, Penancols, and Bermuda, the second giving, in words, a forceast of the probable winds for the next two days over specified sections of the Atlantic and Gulf of Mozico, extending about a hundred miles offshore, and warnings of severe storms as occasion

Radium Emanation in Medicine. The distinguished English surgeon, for Frederick Twees, recently stated that radium emanation is just as effective for curative purposes as radium itself. Assuming that radium is really the valuable therapeute agent which it appears to be, the amounteement is of great unportance. Its data is extremely precious, for a small quantity of radium can require a small productive of the produce practically an unhunted quantity of very cheap emanation. Radium canantons contained in scaled metal applicators are being sent off daily to all parts of England for medical one to use on their patient who cannot attend the Radium Institute. In a space of ton days cemantons equal mentarity value to \$85,000 worth of radium have been sent out. Radium emits three sites of rays, designated respectively by the Greek letters, "alpha," "botal" and "gamma". The first two destroy the healthy tissues of the body when directed at close range, and at greater distance attimitate the abnormal tissues of tumor to renewed growth. The "gamma" rays are those which are desired. The more or less undesirable "alpha," and "beta" rays are filtered out by lead sersons, through which the hard "gamma" radiations pass easily.

### Gasoline Slot Machine

T AKING its one from the fortunes that have resulted from the harvest of pennies dropped into chewing gum slot nuchines, a nd with the adventages of such automatic vending devices apparent, a Michigan company recently has placed on the market the gasoline vending slot machine that is shown by the accompa-ing illustration. The machine, which quite as automatic in action as are its gum vending predecessors, has a numb of features equally attractive to the man in his money and receives line, and to the man who puts in the gaso line and receives the money. In opera-tion, it is merely necessary for the person requiring gasoline to drop a fifty-cent piece in the slot, place the end of the flexible hose in his gasoline tank and turn the crank. The machine is equipped with a gage-visible in the picture-to show whether it is full or empty, and even if a person should inadvertently piace his money in the slot when the tank is empty it is promptly returned at the first turn

of the crank, just as your penny is returned when the chewing gum slot machine is empty Of course as much more than fifty cents worth as is wanted can be obtained-up to the capacity of the tank—though a fifty-cent piece is the only coin that may be put into the slot. So that the device can be used anywhere, regardless of the fluctuating price of fuel, it is equipped with a metering mechanism which can be adjusted to deliver the proper amount of gase line for the amount of money put into

The machine that is shown by the

The machine that is shown by the picture has been installed by a garage proprietor in the city of Lansing, and he is particularly "tickled" with it, for it is particularly "tickled" with it, for it requires no attendant, is positive and unfavoring in action, is always ready to serve anyone with the necessary coin, and ieft to itself dispenses some 200 gallons of fuel a week. As the machine requires no attention once it has been properly installed, it is obvious that garage propri tors are not the only ones who may benefit by its usefulness, anyone may install one and be assured of a profit Not only does the machine run without attention other than that required in filling the "gas" tank, but it is canable of "delivering the any minute in the twenty-four hours and any driver who knows of its location has no need to awaken sleepy garage attendants in the middle of the -provided he is able-to obtain the

wherewithin to get home
On the other hand, it is evident
that a vending machine liable to hold fifty or a hundred half-dollars would be a mag net for thieves unless placed where

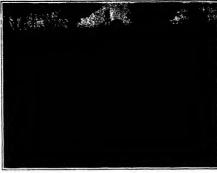

would be constantly under the eye of an attendent.

### Combined Piano Player and Talking Machine

THE deficiencies of the phonograph in the reproduc-tion of plano music are only too well known. In most of the vocal productions, the accompaniment, if played on the piano is often so weak and banjo like that the piece would not suffer much if it tirely omitted. To overcome this defect,

attempts have been made to supply a real accompanient by using an automatic plano-player with the phonograph. But the difficulties of synchronizing the two instruments have hitherto been deemed almost insuperable.

Recently, however, an inventor has succeeded in combining the two instrum so that they are perfectly timed. This he accomplishes by purumatic means con-trolled by a series of perforations in the music roll. On an SS-note player, the duct for the highest note, which is seldom used in the score, is utilized to control the pneumatic coupling. The exact method the inventor is not ready to disclose at the time, as his patents are still pend ing, but apparently the music roll is brought into synchronism with the phonograph record at each turn of the latter It is the phonograph that controls the tempo of the player-plano. The operator of the player-plano does not touch the tempo controlling lever, but he may operate the expression lever, or control the

A casoline slot machine for automobilists

volume of sound by pumping harder or softer as the case may be. Any standard player-plane may be used to which a small attachment is applied, but the talking schine requires special apparatus for the control of its motor mechanism. Otherwise the talking machine is also of standard make and standard records may be

mental record is made by an expert, who

### Pantagraph Which Dunys Steel With a Point of Fins By Henry Harrison Suples

BOM the earliest times it has ! sumed that a given material win he cut only by the use of another and harder material. To-day it is being learned that the hard, keen edge of the cutting tool ible action of the burning tool, by the inse beat of the oxygen-acetylene bl

The old idea of the use of heat in in The our spee of the use or near in the im-pression that a very large quantity of heat necessarily accompanied all opera-tions which required very high tempera-tures. It is now well understood that

re exists, in the oxy-acetylene gas hurner, a work man's tool which is giving him vastly increased capabilities, not only in operations such as welding and fusing, but also in cutting through steel, even of very considerable thickness. Instead of a hard and keen cut-ting edge, the new tool does its work with a point of such an intensely high temperature that nothing can restst it, while the total amount of heat evolved is so

moderate that portions of the metal im-mediately adjacent are unaffected.

The power which such a tool places in the hands of the intelligent mechanic is enormous, and, in fact, can be appreciated only by those who are familiar labor and energy formerly required to cut an irregular shape from a piece of tough and resistant material. To be able to cut out a piece of any desired shape, simply by passing the almost invisible apex of a by pa cone of combining games, is such a revolu-tion in the art of the mechanic, that its

possibilities are, as yet, scarcely grasped.

In order that such a powerful device
may be used to the highest degree of efficiency it is desirable that special apparatus for use in connection with various operations should be devised, and conside progress has already been made in this direction. The ordinary cutting tool has to be used in a machine tool wh capable, not only of holding the work and of providing the desired movements, but also of enabling sufficient power to be applied to force the cutting edge through the resistant metal. When, however, the cutting edge is replaced by the inte

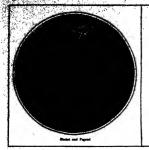

point of the new tool, there is little need for apparatus for holding the work, or for power to propel it. All that the workman has to do is to move proper in Art has the working mass to up it is more the light and convenient the over the surface of the metal which lies quietly before him, and the path of the apex of gases, with its six-thousand-dagree temperature, appears as a clean cut through the metal. The power required for the steel tool is replaced in the new method by another form of energy, by the heat of the jet, an infinitely more direct application than that

which required the transformation into power through the medium of furnace, boiler, and engine, and the losses of transon by belting or electric condu

It is desirable, however, that some method be provided to aid in guiding the movement of the jet over the surface of the metal. The power of the flame renders any faise movement irrevocable, and there should be no uncertainty in its movements. The very nature of the operation renders the use of any ordinary template impracticable, and it is not easy to follow directly any marks drawn directly upon the surface of the metal.

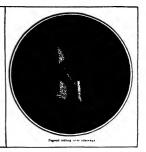

It has been found, however, that as an apparatus originally devised for use in the drafting room for conving and enlarging drawings, the pentagraph may be em-ployed most satisfactority, only instead of drawing with a pencil upon a sheet of paper, it ests through a plate of steel with

distance from the reproducing point, the

### Pégoud's Remarkable Performances

What Coolness and Nerve Can Accomplish

A LTHOUGH the name of Pegoud has been acciaimed in all the newspapers of the world, his remarkable exploits still factionte. He has shown that a cool head culish undreamed of marvels in a flying machine, and that if an aviator is high shough he can always save himself if he side-slips or capsises. As the accompanying illustrations show, Pagood has deliberately placed himself in the most precarious positions conceivable—positions in which unfortunate a fators have found themselves in the past and have plunged to their doom. Pégoud's performances are therefore not to be lightly dismissed as worthless and reckiess acrobatic performances.

A writer in Flysh, who evidently witnessed Pégoud's flights, makes some interesting comments on flying up-side down and on "looping the loop" in a monoplane. There are four definite and distinct feats in Págoud's

re, we are told.

The first is illustrated diagrammatically in Fig. 1.

and in order to a void confu sion it may be these diagrams are drawn in is to say, they show the path of flight as it ears from the side of the machine. If this page is held upright, then the diagram repreas possible does against the background of the sky.

failing to the ground its tail gradually "elevates" and awings the machine, pendulum-like, into a head down position. Pégoud allows this swing to repeat itself sevral times before he finally brings the machine into

Now, setting aside for the moment the natural curios ity of the crowd in the sensational part of the performance, and in the prodigy of a men who does these things with such sang froid, what is its serious or scientific

aspect?
Mr. Norbert Chereau, general manager of Blériot
monoplanes in England, assures our England contemporamonoplanes in England. ary that Pégoud's machine was built as a standard 50horse-power single-seater in 1911, and that the only aiterations made for the purposes of these flights are

1. A new pylon made 12 inches tailer and placed inches farther forward.

2. Substitution of the original tail by one used on

doing the same thing. In a word, t'égond is the per-

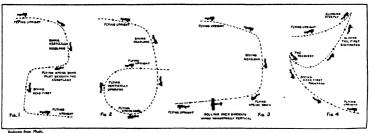

rect numan automaton.

"Instead of controlling the machine, Pégoud lets the machine control itself. From the standpoint of the scientific experimenter, he is the ideal pilot, for he has the lottelligence to eliminate himself at the moment that the machine enters upon its appointed task. He files it with the utmost skill to the desired attitude he turns it head downward toward the earth, he drops like a stone with it until he has acquired the momentum necessury to effect his purpose, and then he calmly deliberately pushes forward his elevator lever and sits still while the machine flattens out on its back

"The amazing thing is that the man himself can retain his composure in positions that are actually nameating to the average person.

"The scientific interest in Pégond's achievements iles in the fact that they are the most complete full-scale demonstrations of the fundamental principles of flight

> beeu carried out. Every aeropiane worthy of the name is inher-ently stable within certain limits. By this is meant that when an aeropiane is prop erly designed. will naturally support it-self on a level keel at a certain speed, and will us turally tend to recover that position if the disposition of its surfaces is

The positions assumed by Pégoud when flying upside down, "Gooping the loop," rolling over sideways, and diving tail first.

ers take place at a great sititude, and to a certain extent that are thus witnessed by the spectators from beneath, which tends, naturally, to foreshorten the ap-

parent vertical distances.

Fig. 1 shows an absolutely vertical dive followed by

Fig. 1 shows an absolutely vertical ure indicated of a "flattening out" speeds doors.

"In an ordinary steep glide," comments the writer in Filphi, "the machine is "fattened out' so as to bring he pliot into an upright position once more in his own special feat however. Pégoud just tucks the head of his Blériot monoplane underneath him, and flattens out

"Having down upside down for some little distance, he then dives again, and flattens out the right way up. The whole maneuver is controlled by the use of the

The wave absenced with the pilot on the outside edge. Pégond dives as mani in order to gain momentum, tucks the nose of his machine under him and the control of the contro elevator lever well forward, he continues his circle until he comes to the top of the arc, where he is flying level, d right way up once more. This maneuver is shown

and right way up once more. This immediate is above in Fig. 2.

"The third contortion involves the use of the warp as well as the elevator. Fulling vertically head down as before and turning on to his back, Pegond warps his wings to the utmost limits of the control and rolls over addeways into an uprint position. This is shown, as clearly as it is possible to do so diagrammatically, the RM 2"

in Fig. 3."
Theirs remains yet one other "standard" accomplishment. Pégoid climbs steeply upward until his machine demos to a itandatill, and so be provides a deliberate tall sides; the machine slips beckwars, but instead of

a standard tandem-seated model. Neither of these afterations affects the principle of the machine or its "nat-ural stability." It is apparent that the purpose of the talier pyion is to set the top bracing wires to the wings at a less acute angle, and thereby to reduce the stress upon them. "This is a very natural precaution in a machine that files, so to speak, habitually on its back, and in which the top wires, therefore, so frequently take all the weight of the machine in the air. Ordinarily, the top wires merely support the weight of the wings when the muchine is on the ground and their severest stress comes, generally, from a bumpy landing. On Pegoud's Blériot, however, they frequently support the entire weight of the machine in flight."

Similarly, the advanced position of the pylon puts the top front wires in a better position to reinforce the wing against the force of direct resistance.

The tandem model tail is larger than that on the

single seater, and gives the greater measure of control that is desirable for extraordinary feats of this descrip-

tion, but not necessarily so for everyday Bying.

"We have, therefore, a perfectly normal seroplane,"
continues Fight, "combined with a perfectly abnormal
pilot and the pilot is abnormal hot in performing compilot and the pilot is abnormal not in performing com-plicated and rapid movements of the control with the dexterity of a Padecewski. but in having the serve to 'sit still in the most trying actitudes while his machine continues properly' to earry out the evolution on which le initially caused it to begin and wiggled his control lever in servous uncertainty, he would end up in a beap on

the ground just as eathely as any other pilot does in a similar plight. Figured is marrislous because he under-stands precisely what his marchine is going to do, and knows precisely how long he desires it to keep on

not tampered with The control of a modern aeropiane gives the pliot ample scope for destroying the natural stability inherent in the design of a machine, and many an accident is caused through the abuse of the control. the proper use of which is, of course, fundamentally necessary for the purpose of steering the machine ou its appointed course

### Ten-day Courses in Agriculture

W inter institutes for farmers, at which ien-day courses in all kinds of rural subjects are offered. are becoming a regular feature of educational work in Canada. For several years such an institute has been in operation each winter at Truro, Nova Scotia. Last year the attendance at this place numbered about of whom 100 were from Prince Edward Island and a large number from New Brunswick, these two provinces subsidizing all of their inhabitants who wish to attend Recently Prince Edward Island has established an institute of its own at Chartottetown. The courses offered here include livestock, poultry, horticulture, soil cultivation, seed selection, and dairying, besides women's courses in housekeeping, domestic science, etc. These courses are given free to all inhabitants of the island who care to take advantage of them, and attendance is further encouraged by a bonus of \$5, together with e transportation, to anyone who makes prior application and theu completes a course satisfactorily. examinations are held, the pupils being only required to give intelligent interest throughout the tessons; thus the older farmers, as well as the younger, are en-couraged to attend. The courses, which are us practical as possible, are given by experts from all parts of

is no reason why man's traps should inflict pain.— EDITOR.

### Is Engineering an Exact Science?

To the Editor of the SCIENTIFIC AMERICAN:

Having read all the matter that has been available to me, I write to ask you if no attempt has ever been made to stablize the hills that have been sliding into the Panama Canal prism Piers in a river supporting long spans often form an nee gorge, and they are constructed spane often form an negarity, and they are constructed in such a way as to offer the least possible opportunity for a collection of ice. It seems to the writer that some means by which the earth could be halted and held is far from an impossibility

That much money has been spent for surveys and

boring on the route of the canal is well known would like your opinion of inginiering as an exact science when it was estimated after exhaustive work that the Culebra cut banks would stand at an angle of about 33 degrees from horizontal, and that in practice they are still moving and at an angle of about 7 degrees.

Cowles, Neb F. A. Good.

[The sides at Panama do not vitiate the claim of engacering to be an exact science. We doubt if even engineering to be an exact secured. We down a even more expensive borings would have revealed the fact that the Culchra material was so mistable as to require a slope of 1.7—which could be demonstrated only when the cut was fully opened Engineering as "exact," if the conditions can be foreknown.—Euron 1

### Reversing the Locomotive

To the Editor of the SCIENTIFIC AMERICAN:

If it is not prolonging the discussion on "Reversing the Locomotive" beyond the point justified by its importance to your readers, I would like to add these few comments

The correspondent in his letter on this subject in the issue of September 20th has very clearly explained how it is possible to retard a moving locomotive with only the use of the reverse lever and throttle. That the above is possible to obvious to anyone who intelli-gently considers the matter, and that it was possible was not denied in my letter printed in issue of July 5th; your correspondent to the contrary, notwithstanding. I lord misinterpreted your editorial comment of June 21st to advocate an automatic stop which would utilize only the reversing power for retardation, and pointed out the asclessness of such a device As to the question of the engineer relying upon the

returdation from the reversing power, if he must first prove to bluself that the air-brakes are in then close the throttle, then throw over the reverse level, and then "gage the steam so that he will get very nearly" the ultimate tractive power for retardation. he would by this time have gone down, in most re emergencies, as a marter to duty. In the case of the wreck at Stamford on June 12th the engineer probably would have had less than 15 seconds to complete the four above operation

It is certainly absurd to advocate makeshift prac-tices which were used in connection with locomotives before they were equipped with air-brakes to be apperior they were equipped with the modern reliable piled to locomotives equipped with the modern reliable air equipment. As pointed out in the editorial com-ments on this subject in the bone of July 5th, when all other means have failed in retarding the train, reversing the power should be used as a last resort, just as a drowning man would grasp for a straw, and should sever be relied upon when there is the slightssibility that the air brakes are of est po is not as easy to determine, quickly, in the moment of mental stress as it might be supposed. At present it seems to me to be only a remote possibility that such a principle could be incorporated in an automatic stor

### Sailing Hydroplanes

To the Editor of the SCIENTIFIC AMERICAN:

I have noticed with interest the development in the last few years of the motor-driven hydroplane, but I have seen nothing of any sail-driven hydroplanes. I am sure that if a cup defender is desired that will run

have seen nothing of any ani-driven pydropianes. In a sup defended is desired that will run away from anything sies driven by the wind, a salidiven hydroplane is what is wanted.

About fifteen years ago my brothers and I used to sail boat roses on the ponds. It was too much trouble to make a hollow-hulled boat, so we fashioned out by taking a ploce of shingle scross one end, sloping upward forward at an angle of shout 25 degrees, then fastening a piece of shingle scross one end, sloping upward forward at an angle of shout 25 degrees, then fastening a cross-bar to a short mast which was stepped in this cross-law and the state of the st that we had a rough hydroplane with outriggers. that we shad a rough syroppiane with outragers. As an observed a short of the but as soon as the sail began to draw it began to rise, and as soon as it had got clear of the water it was "flying." These boats attained surprising speed.

I would like to know if any of your correspondents have ever tried this form of craft. If not, I would like

cone who lives at the seashore to try it and let me ERNEST WELTMER. know what are the results.

### Is the Dunne Machine Inherently or

Automatically Stable? To the Editor of the SCIENTIFIC AMERICAN

In the SCIENTIFIC AMERICAN of August 23rd, page 139, under Acronanties, I see that a flight across the Channel has been made in Dunne's self-balancing

To this aeroplane is attributed a while it is only inherent stability, which is not sufficient

under all circumstances.

The difference between automatic and inherent stability may be seen in my article in the Scientific Aranacon of December 17th, 1910. "Distinction to be made between these properties of the stable of t The difference between automatic and inherent stabil-

out the executed parts.

That I antedate and have the priority over Dunne, Fokker, Lohner and many others, is proven by my patent drawings of 1902, and by my article in the SCHENTIFIC AMBRICAN SUPPLEMENT, 1982, of March 28,

With my acroplane no further experiments could be made for lack of funds, and likewise other now very much needed experiments concerning automatic balance propulsion, etc., cannot be made, for the same reason, propulsion, etc., cannot be made, for the same reason, respectively because there is no experimental station in America, where inventors can get their inventions tried out, without cost to the inventor, who, as a rule, has not rufficent funds for that purpose.

(larkwille, Torm. Thuso. Giron.

#### The Stratosphere To the Editor of the SCIENTIFIC AMERICAN:

To the Editor of the Scientific American: Referring to the last lines of your notice on page 159 (August 30th last) to my paper read at the R. Met. 8. on Air Currents at fifty miles: "These conclusions hardly agree with the prevailing conception of the stratosphere as a region of gentle wind," I may point out that we have no authority for stretching the stratos-phere beyond the limits explored, say up to 15 miles or saibly a little mo

saibly a little more. The velocities at fifty miles are quite in agre

with previous records of moteorie trains, but rarely if ever before have such complete records been available by which such definite results could be obtained. These results have been confirmed by the great authority motoric ecience, Mr. W. F. Denning, of Bristol, wo ing to a large extent on independent data

J. EDMUND CLARK.

Whether the stratosphere extends up to fifty miles is mainly a question of terms. Dr. Alfred Wegness has roomely incroduced the idea of a "hydrogramphere" beginning at about that altitude, and of another "sphere"—the "geocoroniumsphere"—very much ligher; but most meteorologists still think of the atmosphere as but most meteorologisal stat large of the autoopsees and divided into two main strata—the troposphere and the stratosphere, or isothermal layer. We did not intend to question the accuracy of Mr. Clark's observations—which are in accord with those that have been collected and discussed for several years past by Dr. C. C. Trow-bridge in this country—but to point out the contrast that certainly exists between all these meteor train observand an idea that seems to have crystallized in tions and an idea that seems to have crystallized in recent meterological literature; vis., that the whole upper atmosphere is a region of gentle winds. A marked falling-off of wind velocity in passing from troposphere to stratosphere is regularly shown in aerological observa-tions, notwithstanding the great horizontal contrasts of temperature that exists within the stratosphere at all levels that have been sounded. Whether there are theoretical reasons to expect stronger winds at high levels—and whether it is not a mistake to insist upon the "non-convectional" character of the stratesphere— are questions that well merit the attention of students of atmospheric physics.—Entron.]

### Rearrangement of Star Mana

To the Editor of the SCIENTIFIC AMERICAN: I noticed in your columns for printing the personal letters of correspondents upon different subjects a letter is term of correspondents upon universe stageous a rever recently which had to do with the prevalence of error in our American geographical maps or charts. Why can we not take up the matter of the errors in our

sal star charts of to-day? The allegor allegorical star charts of to-day? The allegorical star-charts of to-day are covered with a system of figures, and hardly any of them agree as to the proper placing of those which do exist upon our maps, and truther they are apparently placed at random in most cases. We have sufficient evidence in hand now to enable us to place these figures very accurately or arbitrarily. At least usudo as he done with the most vital figures of the northern heavess proper. The original outlines in each case are presidently making eternal in so far

At least such can be done with the most vital ngures of the northern heavess proper. The original outlines in each case are practically speaking eternal in so far as man's period of existence on the earth is concerned. Each figure should be tied to the starry outlines constituting such figure in a rigid manner.

A great number of the inhabitants of the celestial

valit do not belong there at all. On the other hand, many of them are placed in a position foreign to that which they should occupy. In a great many cases they lie entirely outside of the territory which they should

cover.

In a word, we need a new survey of the sky very badly. Our star charts are very obsolete in this respect.

Can we not get our astronomical machinery busy upon the table to the sky were unti-date or within back to. the job and make a more up-to-date or rati date set of charts.

The Great Bear or Ursa Major will lose to the Lion and Buil of course. In fact, he will lose out entirely. Copheus Buil of course. In fact, he will iose out entirely. Cepheus will be seated upon his throne and adjusted to the proper position and proportions for the first time in some thousands of years. Andromeds and Prometheus will be rivals for the possession of the huge human figure which overspreads the galaxy from the region of Lacotta. to Ophiuchus, or a distance of some two thirds way

which overspreads the galaxy from the region of Lacorta to Ophiuchus, or a distance of some two thirds way across the visible sky.

Off in the southern heavens we shall have to undertake a general overhauling and must of necessity "paint that part of the town red." Here we shall have to recurrect the menagerie or circus of animal forms which belong there by divine right, deterioning a number of usurping inhabitants who are undoubtedly aliens in that locality. The monkey or age tribe predominate in the region of Pegasus and Aquarius and are very naturalists and real in form and proportions. The three monkeys in southern Aquarius are very lift-like little follows and seem very intent upon their besiness, whatever that may bu. The head in onlymetics with the lower fish of Pisces approximates very closely to that of a dog, still it is not difficult to see how the Egyptian could have made of it the smooth dog-cared aps representative of Thot. It is also very apparent that it has been seen as quarding the entirance to the lif-capital place of this locality of the heavens.

We have the major figures of the notibern heavens proper very accurately destrining from. Will you start a revolution to outst the many allows and saurpers as revolution to outst the many allows and saurpers as revolution to outst the many allows and saurpers as revolution to outst the many allows and saurpers as

a revolution to outs the many aliess and neurpers as well as to readjust the native inhabitants to their proper spheres? The data are self-evident truths, once our at-tention is called to the different forms. Pueblo, Colo.

### Earthquakes and the Panama Canal

A Study of the Geological Conditions on the Isthmus and What it Reveals

THE earthquake belts of Central and South Ameri are approximately coextensive with the regions of fairly high mountains. Within the Bepublic of Panama mary man mountains. Within the Deputher, or Januars there are few, if any, mountain ranges, properly so-called; but there are high mountain groups. The older geographies informed us that the North and South American Cordillerars were practically use continuous chain from Alaska to Cape Horn. This is quite incorrenti from Annua to Cape roots. Into its queen new-rect, for the mountains of Panama, Casta Rica, and some of the other Central American republics are younger than are the great ranges of the western States, and are units quite distinct geographics! If from the greater northern and southern continental ranges. Furthermore, they have had a different origin, for they are not due to folding by lateral pressure, as the mountains of western America chiefly are, but originated from intrusions of volcanic rocks, as necks, cores, masses (Fig. 1) and irregular dikes (Figs. 2 and 3). These intrusive rocks are of five broad types, which, given in the order of their importance, are: basalts diorites, andesites, granodiorites, and some rhyolite. Ir their original molten condition, they were injected up through volcanic agglomerates, brecelas, and tuffs; and sandstones, argillites (Figs. 2 and 3), limestones, and ds, mostly of Oligocene age. Most of the bedded rocks cut by these bodies of igneous, or volcanic rock, are not very well consolidated, except in the vicin ity of the higher mountains. There they have undergone some induration and slight baking, due s of formerly hot lava rock which was injected into them. The basait, and esite, and rhyolite intrusions are mostly post-Oligocene, and seem to be gely Miocene in age. The diorite is, at least in part, pre-Oligocene, probably of Focene time. that the earthquakes are coextensive with these moun-tain groups is evidence that the latter, at least locally, have been mushed up beyond the stability of their foun dations, and are even yet slowly settling back to adju ment. Both Gold and Contractors' Hills ure, on a small scale, such settled down masses, as will be explained later. There are only two peaks within the Canal Zone that reach up to elevations of approximately 1,000 feet, and there are no peaks within thirty miles of the canal that are higher than 2,000 feet. Not within one hun-dred miles could one find mountains over 4,000 feet in elevation. Therefore, the canal is far removed from the at mountain masses, the settling and adjustm which might cause cumulative stresses, that would culminate in rock ruptures great enough to give destruc-tive earth vibrations. Furthermore, the relative weakmost of the rocks within the Canal Zone region prohibits the accumulation of stresses sufficiently great to cause violent rock rupture, with concomitant earth jars of destructive proportions. Theoretically, then, we would expect the Canal Zone to be well outside the Central American earthquake belt. This is quite in accordance with the facts of observation as given in a long and fairly complete record of the quakes that have occurred from the time of the Spanish conques to the year 180

The Earthquake Record of Panama.

In all last states and off to the presents only two covere shocks were noted; to not of these, in 1621, destroyed many of the buildings to Panams, and one in
1882 damaged several buildings and bridges, and locally
threw the rallway track out of alignment. In Colon
the latter quake is said to have opened a few creviers,
and to have been attended with some fatthicts. Very
many smaller shocks have occurred, and since the installation of seismographs by the Jathman Canal Commission, numerous termors, most of which jare detectable only by instrument, are recorded every month.
The liability of the casal to injury and destruction by
earthquakes since 1821 would have affect is that
no earthquakes since 1821 would have no encountered it,
and the shock of that year, though severe seough to
shake down adobe houses, and even some masony
structures, would have had no serious effect on canal
slopes, and little effect on such rock founded, solid concrets structures as the looks.

It is interesting to note the difference between earth tremore, caused by a heavy black and those due to sarrhéqueise. This difference is clearly registered in ""Trembignessés de Turre et Braytion Voicalques au Castre-Anorique, par 9. de Montesseus de Baljora, p. di, fecilés ées déchose Matardies de Bane-et-Léra, 1989.

the different effect which each produces on the sciamograph. The instrument at Ancon is a 100 kilogramme, Bosch-Amori, which magnifies earth waves too times.

Aucon Quarry has been the theater of considerable heavy blasting. It is 3,100 feet S. 61 deg W. from the instrument. Some of the blasts there, and their results, are as follows:

 April 8th, at 5.25 P. M., 10.700 pounds of dynamic cylloded, recording stancia awang 20 millimeters north and 0 millimeters south, 75 millimeters east and off the paper, thus giving no back swing to the west.
 March 2nd, 12:30 P. M., 6.000 pounds of dynamic

 March 2nd, 12:30 P M, 6,000 pounds of dynamite gave a vibration record of 6 millimeters north and 1 millimeter south, 11 millimeters east and 5 millimeters west.

June 2nd, at 5:10 P. M., 4,000 pounds of dynamite swung the stenctis 11 millimeters north, 2 millimeters south, 5 millimeters cast, 2 millimeters west.
 April 30th, 5:15 P. M., 1,200 pounds of dynamite caused the stencils to swing only ½ millimeter on each caused the stencils to swing only ½ millimeter on each

side of both lines.

5. On March 20th, 1,900 pounds of dynamite showed no north-south, and only 1 millimeter of east-west

with uncounted the state of the

In the larger blasts at Ancon Quarry the violent push given to the rocks by the explosion threw the recording stoodis over toward the east and north, with a very small aving back to the opposite directions. The motion was accomplished with not more than two, and mostly one, quick strokes, occupying 2 to 3 seconds or time. After that the vibrations were very matute and much slower, and died out antirely in 10 to 15 seconds. In the smaller blasts the distance was great enough to By Donald F. MacDonald Geologist Isthmian Canal Commission

cushion completely the first violent imputes given to the rocks, because the swing of the recording structito each side of the lines was equal. In the case of the subaqueous blasts the distance was also great enough to cushion the first violence of the shock.

A Study of Some Blasting Effects.

Some other blasting effects near Culebra were recorded on less smalltly instruments, and these, translated into approximately the terms of the standard
instrument at Ancen and Gatin, are as folions. Fourteen 24 and 28-foot holes, fonded with 2250 pounds of
dynamite, were exploded within 1,100 feet of the instrument, and gave a maximum amplitude equivalent
to 20 millimeters. Therefore an increase of nimest 120
per cent in the dynamite charge, gave an increase in
the recorded effect of only 40 per cent. Ibid of these
blasts were in comparatively soft angiliacense rock, and
were situated almost 30 feet below the top of a 200foot cut alope. This lucation, so close to the clage of a
high, steep slope, would, of course, increase the tendency to vibrate. In general, it may be said that in blast
of 5,000 pounds of 60 per cent dynamite would not
rapider on the standard Ance instrument at a distance of more than 2½ miles, under the local geodaction
conditions. In summary, then, it may be said that the
conditions. In summary, then, it may be said that the
conditions in summary, then, it may be said that the
conditions in summary, then, it may be said that the
conditions in summary, then, it may be said that the
conditions in summary, then, it may be said that the
conditions are comparatively rapid and apparently almost
wholly compressional. They consist, in quite limited
degrees, of large, slower waves or movements and sandirequired productions. Entitlements because in the other
hand, are slower and more undulatory, but they, ton,
cored major mudulatory motion, or impulses, together
will minor oscillations. The chief reasons for this
difference prolability are

a. Blasts are near the surface where the rocks are uder slight pressure, and, therefore, more chastic

under alight pressure, and, therefore, more clastic
b. Earthquakes are relatively much more decessented and are generated where the rocks are under stresses which greatly reduce their clasticity

c Blasts are quick acting shocks like the blow of a hammer.

d Earthquikes result from slower acting rock rup-

In addition to earth waves, blasting also geocentee atmospheric waves, or compressions, which travel with the same velocity as sound, because the atmospheric harand he sound from the blast always, arrive domatinacously. The earth waves from the blasts travel much more rapidly thus sound. The desper the blast, other things being equal, the greater his proportion of its energy goes into earth waves and the loss into almospheric waves. The latter often far houses more than do the earth waves, and for this reason it was for a time held by some that the "doke" or surface blasting tended, more than deep blasting, to promote sildes in Cutebra cut. Such, however, is the opposite of the fact Exposed in the walls of Culebra cut are sections of

two large volcanic cores, the Gold Hill mass and the Contractors' Hill mass. Both of these have been faulted down (Fig 1) some innufreds of feet through the surrounding softer sedimentary rocks. The sheared some around the margin of each is from 2 to 10 feet wide, and the downward drag of the Gold IIIII mass has pulled small masses of lava down over 100 feet from a former flow. This is all exposed in the face of the cut as shown in Fig. 5. Such a frictional pull, coupled with such a wide sheared zone, indicates a down throw of at least 300 feet, and perhaps much more (lold Hill rises to over 600 feet above sea-level, and has an ap-proximate area of 1,500,000 square feet. If we call its depth 1,000 feet we have a mass which weighs approxi-mately 112,500,000 loss. This mass has been fautted down at least 300 feet, but to accomplish this probably nired a considerable period of time. If, for the sake of comparison, we assume that it dropped freely one only, we find that by such a drop it would exert a ssure on its base, or strike with a kinetic energy of 225,000,000 tons. Now, P Gerald Sanford ("Nitro-Explosives," page 286) records that one kilogramme of pure ultroglycerine on explosion exerts a pressure of 19,151 kilogrammes, therefore a blast of 18,000 pounds of 60 per cent dynamile, equivalent to 10,800 pounds of nitroglycerine, would exert a pressure of 106,831 tons, only about 1/2,106th part of the pressure developed by the down drop of Gold Hill one foot. Broadly speaking,

### Rudolf Diesel: An Appreciation

### The Significance of a Great Inventor's Work

### By Henry Harrison Suplee

THERE are inventors and inventors!

The old-time idea of an inventor was a man who, suddenly, in some occult manner, cancelved the idea of something new wonderful, and valuable, and who then spent the rest of his life trying to get capitalists interested in it; a man who was lucky if he did not die poor and enrich others after he was gone.

The modern inventor is something quite otherwise, a trained engineer, who, perceiving the defect in some department of engineering work, directs his nind to the solution of the problem, and, bringing to it ample theoretical knowledge, carefully and accurately works out practically the application of the theory to definite success. Such modern invention is typified by the work of Rudoif Delenia.

in the summer of 1897, the Verein deutscher Ingeni-

ears was holding its convention at Casael. During the meeting the members of this important engineering soldiers of the important engineering soldiers were livited to wituses the operation of a new type of host motor, the result of the application of modern thermodynamic principles to the problem of securing maximum efficiency in the development of mechanical energy from the combustion of liquid fuel. That motor was the Diesel engine. As then shown and enthunisationally admired it was practically the earne as that which is now known all over the world as the most efficient heat motor in existence, and the greatest advance in the generation of power from heat since the invention of the sensarate condenser in Wall the

from neat since the invention of the separate condenser by Watt. Rudoif Diesel, born in Paris in 1858 of Bavarian parents, received his early education in the French capital, and thus acquired the easy fluency in the French language which made him so acceptable a speaker before the meetings of the Bociété des Ingénieurs Civils de France The outbreak of the war in 1870 rendered it necessary for his parents to leave France, and a portion of the time after this was spent in England, so that, to a thorou owledge of German and French. there was udded an equally great proficiency in English, rendering the young man a true cosmopolitan in training and thought A course in mechanical engineering at the Münich Polytechnic, under such masters as Schröter, in mechanics, and von Linde, in thermodynamics was followed by an excellent bustwas followed by an executive business training in charge of the Linde refrigerating mechine interests in Paris. Thus there were brought to the attention of this acute and broad intelligence the fundamental ms in the relations between thermal and mechanical energy in

connection with gases under high pressure. The first result of this condustation of theoretical and practical ideas to be given to the public was a small book on-titled "The Theory and Construction of a Rational Heat Motor," this appearing in 1886. Here we see the scientific man, working mentally to consider the necessary elements of a rational method for conversing heat into work. He approached the subject along the lines of this master, von Linda, considering the various cycles possible, and selecting the so-called Carnot cycle as offering the possibility theoretically considered, of attaining the maximum thermal efficiency. Having chosen the cycle, the best methods of attaining it were considered, and with these came also the knowledge of the importance of operating with a high compression ratio in connection with high efficiency.

These things determined, there followed a study of

These things determined, there followed a study of the best practical approximations which might be expected to these theoretical conditions.

We see here a complete reversal of the older ideas of inventors, of those men who, having conceived some kind of a machine, proceed to try it out experimentally, and after many failures, succeed in hitting upon something which will work, and which may, after many discentaging experiences, be developed into successful operation. The motor of Diesel, on the contrary, was first worked out wholly on paper, as a resisonal application of theoretical principles, and then and not until then, was a machine built. At this time the best thermal efficiency of the stewn agine, and that is large units, was about 15 per cent. The early Diesel engines of small size, 90 to 90 horse-power, showed immediately an efficiency, or percentage of total heat vatue in the fuel converted into power in the cylinder, in present Diesel engines in From 42 to 48 per cent, or nearly three times the efficiency of the steam engine, and double that of the ordinary gas eagine. Even when the frictional tools were the mechanism of the machine are deducted, the actual efficiency in the power available for useful work has reached about 35 per cent, and this because

Dr. Rudolf Diesel, the inventor of the Diesel engine.

of the scientific application of theoretical principles to the design of a rational heat motor.

Apart from the adoption of an efficient cycle, and the new of high compression ratios, the Disset engine has accomplished an important commercial result in two ways: the heat of the compression is sufficient to ignite the their charge directly in the cylinder, thus eliminating altogether the carbureter, that source of so many amoyances in ordinary combustion engines; while the absence of any ignifiable charge during the compression struke represents patched in monoscillos.

The intimate admixture of the pulvarized liquid fuel, into the midst of highly compressed air much above the temperature of ignition, pulses shed air much above the temperature of ignition, also insures complete combustion, even when heavy and ordinarily difficult fasile are used, so that all liquid finels may be used indifferently, from the light gasoline to the heavy distillate readions. Gas tar is readily and fully consumed, and vegetable oils, such as penunt oil or castor oil, are freshy converted into power in the Dissel engine. The revolution which such a machine is creating in the development of power must spewer. In nearly all the countries of the dyflined world the Dissel engine is being manufactured, and the leading constructors of Germany. France, Switzerland, Russels, and Swoden, as well as

England and America, are inserested in this modera power machine. It proposis practically all the effective submarine vessels in service, it is sintering into the merchant marine, and unless the ship on the water is superseded by the ship in the sir, it must enter the navel service of all progressive powers.

The contrast between this modern method of produc-

The contrast between this modern method of producing power from fuel with the older machine, the steam engine, is interesting. Instead of burning fuel inefficiently under a boiler, to convert water inselficiently into steam, convayed inefficiently through a plue, to be expanded inefficiently in a cytinder, the fuel is slujested as a spray into a mass of dense, highly heated sit, in the very cylinder where the power is to be generated. Closely crowded into contact with ample sit for its complete combustion, the fuel is completely burned to the

gaseous state, without any readuse, pushing the platon before it to make room for its increasing solume and that of the expanding air which it is beating, but without increase in pressure. Then, expanding along an adiabatic curve, it yields up energy which, in the cruder machine, was largely dissipated uselessly, and, like an expanded spring, is released.

There is probably no more laborious and exhausting work demanded of human beings than that required in the stokehold of a great steamer; and no more impressive demonstration of the result of the work of Rudolf Diesel can be given than to compare the hufernos before the furnaces of a marine boller with the cleanity, cool, and silent engine room of such a vessel as the "Salandia" with its Diesel engines.

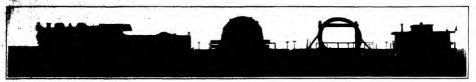

In the University of Glasgow there is chercished the model of the Newcomen engine upon which Newcomen engine upon which James Watt was working when he conceived the idea of the separate condenser. In the musuum at South Kansington there are some fragments of Stephenson's "Rocket." There is cause for gratification that in the new buildings of the great German Museum at Münich, the original Diosel engine is preserved as a monument of the result of the union of theory and practice.

#### A Hydro - seroplane Flight From Newport to New York

On September 20th William Thaw of Pittaburgh and Sinaw son Macgordon started from Newport in a Curless sping loat They port in a Curless sping loat They landed on Oakwood Heach, Raten Island, on October 6th. The most eventful portion of the trip was the journey from Morris Cove, Conn., to Statea Island. In Sping down the Beast Elver the aviators had to pass

East River the aviators had to pass under three bridges, which they did with ease. Indeed, the bridges gave them less concern than the smoke and cinders in the atmosphere of New York. This is one of the longest hydro-acreplane journeys thus far made in the United States.

An Official Register of Selected Plants will abortly be established in Hungary, if the recommendations of E. Grabner, director of the Royal Hungarian Institute of Plant Selection at Magyarovar, are sceeped by the government. The objects of this register will be, on the one hand, to protect the rights or plant-brieders and prohibit the illegal sale of varieties improved by them, and, on the other, to afford every guarantee to the purchaser of the stelst selection of the variety which has produced the seeds he whiste to buy. This guarantee will not extend to the quality of the seeds (e.g., their power of germination), nor to the value of the crops, but merely to the identity and purity of the variety. Detailed plans for this undertaking have been submitted to the Ministry of Agriculture, including provision for the Inaposition of the plants that it is desired to register, sepellocations to be employed in the records, registration fees, test sowings of the registered plants to be magile by the Institute, etc.

Special train transporting the 46-ton cover plate and 9½-ton curb plate.

### Transporting a 46-Ton Cover Plate

### A Railroad Bed Lowered to Accommodate the Castings

"I HE great aqueduct siphon which passes 1.114 foot below the Hudson Sitve is to have its shaft at the west bank closed with an enormous concrete plug, but it is essential that the shaft at the case side be provided with a removable cover so that access may be had to the tunnel when required. Those who have read the article in the SCRENTING AMERICAN Of June 24th, 1911, will recall that the aqueduct comes down to the Hudson Sitve from a considerable elevation, so that

a heavy head of water must be contended with even at the very top of the east shaft, and it has been necessary to design a closure of this shaft which would withstand an enormous unward thrust.

stand an enormous upward thrust. The shaft is 14 feet in diameter. In the concrete lining, 48 feet below the top of the shaft, an anchor ring is embedded. This ring holds the heads of 38 anchor bolts, sech 4½ inches in diameter and 50 feet long, made of nickel-chrome steel These bolts pass through a ring at the top of the shaft known as the "curb ring," and through bolt holes in the dome-shaped cover that fits upon the curb ring. To make a perfectly tight joint between the curb ring and the cover, lead wool calking and a special rubber graker are employed.

phoyen.

The curb ring and the cover were very difficult pieces to cast and also difficult pieces to transport to the site of the shaft. The foundry work was done by the Midvale Steel Company, while the task of installing the huge steel members is in the hands of the T. A. Gillespie Company.

The total weight of the cover piece, machined, is 92,500 pounds. Its outside diameter is 17 feet, while the outside diameter of the curb ring is 17 feet 10 inches. At first it was proposed to ship these castings by team to the Delaware River and thence on barges to Storm King via the Raritan Canai, because th was considered impossible to send them by rail. However, further measurements showed that by placing the castings in well cars so that they could project be low the floor of the car to within six inches of the rall, they could be trans-ported over the Pennsylvania Railroad if taken by a round-about route. The castings had to be placed on edge because, obviously, there would not be enough lat-eral clearance along the roadbed if they were placed horizontally. The task of rting these unwieldy castings in npright position was no small one, particularly in the case of the dome-shaped cover. A frame-work was built up on the car as indicated in one of our photographs, and this was well secured with the bars, running lengthwise

and crosswine

Shirt Harding

One of our photographs shows the trait which transouted the castings from the works at Midvaie to Greenville, New Jersey. It will be seen that the castings project well above the top of the locomotive and the caboose, even though the curb ring was supported in a shanting position. At one piace, namely, at Wissahickon Arenus, Philadelphia, it was impossible to passe thick makes the property of the property of the railroad bed is fines. In order to secure the proper grade at each side of the bridge, it was necessary

the trail under a bridge, and so it was decided to lower the railword bed 18 inches. In order to secure the priper grade at each side of the bridge, it was necessary to reconstruct about 200 face of the readbook At another paper the continue to order everal bolts when painting under a bridge. The shipment was made on a fanaley, and its besk 14 hours to transport the continue fraction, vary topic-heavy and would start continuing every work, vary topic-heavy and would start continuing every once in a while. This made it necessary to stop the train frequently until the oscillation quieted down. The castings have since been shipped up the Hudson

The castings have since been shipped up the Hudson and delivered successfully to within a few feet of the position they are to occupy on the shaft.

One of our photographs shows the cover under test in the Midvale shops, and fastened down with special bolts, so that it could be subjected to a hydraulic pressure of 250 pounds per square inch, for 24 hours.

The cover plate in the shop being subjected to a pressure of 250 pounds per

How the castings were mounted on the well cars.

In order to make this test, it was necessary to construct a bottom plate for the dome, 17 feet in diameter and 12 inches thick. The casting of the cover as it came from the foundry weighed 15%,000 pounds, with eight 154-inch risers. After these had been removed, the weight was still 114,000 pounds.

### Foreign Meat Regulations Established

THE Secretary of Agriculture on October 4th published rules and regulations governing the important on of mest and inest food products to carry out the mest section of the tatiff act approved on October 3rd. The regulations provide for foreign certifications ato aste-mortem and post-mortem laspection in countries which the animals are staughtered. In addition mests will be inspected by the Department of Agriculture at ports of entry before schneiden. Attached to

the regulations is a full list of veterinary inspectors in foreign countries whose certificates are acceptable to the United States.

The regulations also place foreign means after entry into the United States on the same basis as domestic meats. Herestofore imported means have been governed entirely by the food and drugs act, and have been excluded from the establishments under the inspection of the Bureau of Animal Judustry under the mean tim-

spection act. Under the new regulations imported meats are placed under the meat inspection act after entry and thus are admitted to federally inspected establishments and are governed by the same inspection system as heretofore has surrounded interstate connectee in domestic meets. The general rule is that no meats that are diseased, contain harmful dyes, chemicals, preservatives, or other ingredients which render such meat or meat product unsound, unlicalifial, nuwholesome, or unfit for human food, will be admitted

#### Mesothorium Treatment for Cancer

THE London Times correspondent in Munich reports that all Germany is ed with the idea of procuring mesotherlum for use as a panacea for cancer This radioactive substance is obtained from the thorium waste in the manufacture of gas-mantles. For therapeutic use a tiny particle is luclosed in a silver covering pierced with minute holes; the box is placed upon the part affected with cancerous growth, and is said to slowly but surely eradicate the disease, though leading physicians are disposed to reserve judgment on the subject Meanwhile, snys the Times, there is hardly a town of Importance in the country that has not voted a large sum from the public funds for the purpose of purchasing some of the costly material, and where public funds are not forthcoming, concerts, businers, and the like are the means resorted to in order to raise money for the same bur-

### Trans-Greenland Expeditions

A PIRESS desputch of August 15th from Copenhagen reports the successful ternatation of the Jamids expedition across Greenland, under Capt. Koch. The Jarry of four, one of whom was Dr. Affred Wegener, the well-known Germain meteorologist, disembarized at Cape Bismarck, on the northeast coast of Greenland, in July 1812. Octube to the lowes of their

July, 1912. Owing to the loss of their motor-boat and an accident to Dr. Weycener their departure for the luterior was delayed until the latter part of September, when the leve of Dove Buy lecame heavy enough for siedding. They wintered in Queen Louise Land, as planned. (New Neuerrice Augusta, April 27th, 1912, p. 375, and November 201, 1912, p. 376, and the party broke camp and saired on the 750-mile journey to the west costs. After encountering sovere bilizards and killing all their ponies for food, they were rescued at Proven, near Uparturik, July 1856, News has rescently been received of a trip last year across the northernment part of the Island by Knud Ramussean and Peter Freuchen, in the course of which "Peary Channel" was proved to be non-existent; benefar Peary Landie not as Island, but part of Greenland.

### **Edged Tools** that are Personal Friends

There's something about a longused pocket knife or razor that takes it out of the class of "common things" and makes it a per-sonal friend—something to be treasured and cared for because of its long and faithful service.

### KEEN KUTTER

-pocker knives and safety razors-have proved and are proving "personal friends" to thousands of busy men whose hurried lives demand instant and unfailing service. These little edged servants have the steel that takes and holds an edge through "thick and thin"—the shape and "hang" to fit your hand and your face, without cramping the one or mis treating the other.

Keen Kutter pocket knives have strong, whip-like springs; firm, well-riveted handles and general fine finish. Keen Kutter safety razors—both standard and junior—have the proper angle to meet your face fairly and squarely and to shave you clean. They never scrape nor pull nor miss a hair.

Try those perfect knives and razors. If you do, and for any reason are dissatisfied with your purchase, your money comes back.

If not at your dealer's, write us.

### Steel With a Point of Flame (Descinded from sace \$60.)

The state of the s

applicability of the apparatus to the manipulation of the oxy-acetylene jet is avident. The jet is attached to the reprong point, and carefully adjusted the proper height above the surface of the metal to be cut, and when the heat is started the movements of the tracing point und the desired path on an adjacent surface, cause the metal to be cut in ac

ordance with any prearranged plan.

It is evident that this adaptation of the antagraph enables the use of templates o be readily effected, so that any number of pieces of similar shape may be cut, while the skill required of the operator is limited to the general manipulation of the apparatus. When, as has been found advantageous in some instances, the trac ing point is fitted with a power driven wheel, the effort of the mechanic is limit-ed to the guidance of the point, and a minimum of strength is required.

It seems altogether possible that this combination of burning jet and mechanical guiding apparatus is only the begin-ning of a transformation in machining methods, which may mean a much wider replacement of the older form of cutting tool than had until recently been thought

#### How One Express Company Proposes to Compete With the Parcels Post

NEW scheme is afoot which, for the A dweller in the modern apartment house, will tend to reduce food prices and make it more convenient to obtain fresh table supplies. Strangely, this school sprang from the attempt which a large express company is making to retrench itself from the inroads in its business which the Parcels Post has made.

Before the days of the modern spart

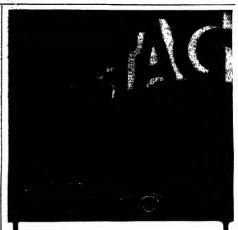

Before the days of the modern apart-ment building, people generally lived in houses with plenty of cellar and pantry room. They were able to buy the sup-plies for their tables in quantities, store them away and use them as they were needed. Buying in quantities enabled them to save on the price of many foods.

Moreover, the housewife was not forced
to pay for the same high standard in service. The up-to-date retailer must meet heavy expenses as to delivery and stor heavy expenses as to univery and so-fixtures and decorations, in order to meet competition. All of this is charged to the consumer in high prices. The problem reolves itself into answering two questions: (1) How can apartment dwellers buy in quantities, and (2) how can they eliminate from the prices they pay, the expenses of retail dealers; and, if possi-ble, of all intermediaries that stand beselves and the produ

The builders of the best apartments are adding to the accommodations every ear, and in many instances refrigerati n a central plant is already provided

If in such buildings an additional oold room in the besement were added, it a producer to deal direct with the entire building as a unit, instead of each individual family purchasing separately from etail dealers, particularly in co with their supply of fruits, vegetables butter, eggs, and other similar staples.

The express company in question is n was express company in question is now trying to assist in a more economical dis-tribution of products by bringing them directly from the farm to the table. If the cold storage room suggested above were provided, they could arrange to bring the producer and one single distributor, perhaps the superintendent of the build-ing, together, and in that way bring about direct shipment by express from the farm to the apartment building. The result should be a continuous supply of absoshould be a continuous supply of abou-listly fresh produce delivered within a down indexe after being gathered in the feel, and at lower prices than it is now possible to secure them through the exist-ing compliance and expensive crustes of injustmentom. The breefit should be a

### Hupmobile

TWO or three weeks ago Hupmobile dealers from all parts of America and Europ
as well came together in convention at the factory to see this new car. And one ma
swept the convention by saying what everyone else had thought but had not said. For ten minutes he had been telling of the hold of the Hupmobile on his big Western territory; and the crowd went wild when he suddenly drawled, by way of climax:—

Boys—when yuh talk to me about competition—1—don't—know—what-mean. I never met up with it!"

And do you know, my dear sir—you who are thinking of buying a car—that this dealer merely expressed a condition that exists everywhere.

Stop and think-have you ever heard any but kind words of the Hupmobile?

Isn't it always spoken of separately-by itself?

lan't it always singled out, and not grouped, as other cars are grouped together in a low priced class?

And do you know why?

### Why This 1914 Car is Unique and Alone

The Hupmobile is in a class by itself because it has a sturdy presed steel frame. The Hupmobile is in a class by itself because it has a sturdy presed steel frame. The Hupmobile is in a class by itself because it has a pressed steef Pullman body

The Hupmobile is in a class by itself because it has an individual, distinctive design.

In this way the best farm products at rices below those of any retail store could be placed at the constant conveni

#### Important Progress in Airships By C. Dienstbach

THE new Zeppelin which made its first trial trip September 6th, differs so essentially from the many new craft of this type recently turned out at Friedrichs hafen, that it marks a new epoch in aero nautics. The big dockyard was length ened to build it, and an entirely new as-sembling shed is being planned for its successors. This new vessel is the "L. II.,"
the second airship for the German navy, and the changes are the outcome of the experiences in trying to make this type "weatherworthy" as the battleship whose consort it will be is seaworthy. There is every indication that the naval Zeppelin become a kind of aerial "dest

In the "I. II." the displacement has been raised to 27 tons (29,837 cubic vards). The vessel has a length of 487 et and beam of 50 feet. The dimens of existing sheds more easily permitted increase in beam than in length. To pre-serve the same strength and lightness at larger dimensions, the weight has been more evenly distributed by the addition of a third car in front of the two cars fore and aft. This new car is used only for navigating, a regular "bridge" with ouse, chartroom and all other paraphernalia. The passageway is in the in terior of the hull, and the cars are closer to the hull—to save shedspace. The old front car has been turned into an ordinary engine room, identical with the rear car, and it now also contains two motors

Hence, the "L. 11." is driven by four separate engines in two separate engine Without being heavier than the former type, the new Maybach motor de velops a maximum of 225 horse-power in place of the former 145, giving a total of 100 horse-power for the new ship. It is claimed by the builders that this new type is the first which might cross the ocean from Europe to America without undue risk

The first trial trip, lasting half an l was entirely satisfactory.

### The Current Supplement

A N article by J W. Fewkes on the geographical and historical significance of stone monuments is full of mos interesting information.-H. Brot contribhydrogen from water gas by liquefaction. In this process the lowest temperature ever employed on an industrial scale is attained -205 deg. Cent. below the freezing point of water.-J. T. Morris reports on an investigation of the wind-pressure near a cylindrical rod. A very neat electrical method of measurement is employed in this research.—W. W. Peters writes on in this research.—W. W. Peters writes on the development and present and future importance of the port of Galveston.—B. H. Bradbury contributes an article on cololds and crystals-two worlds of matter.

Bathing Suit Improvement Needed.— Now that the subject of bathing suits is attracting considerable attention it seems well to refer to and suggest a remedy for a difficulty attending the use of the ordi a dimonity attending the use of the ordi-nary equipment. A jersey suit when wet is hard to get off. Why cannot it be provided with suitable fastenings, say the glove fastener snap variety, so arranged mand with field itsel is Sherard.

Its Sherard tch, or rust.

The Nitrogen-filled Lamp The Nitrogene-Sided Leany The Nitrogene-Sided Leany The Temporary to the American Company of the Management of the Manag making the filaments as well as in the methods of exhausting the lamps were

even in the nope that some night lead to an improvement in the life of the lamps. Anything which would accomplish this result would render it possible to do the more desirable thing, namely, to increase the efficiency without sacrificing the life.

enting on the discouraging resuits of this empirical work, the General Electric Review states that "It was possible to improve the lamps from 10 to 20 per cent in life by certain means, but this corresponded to possible improvement in the efficiency of only a few hundredths of a watt per candle."

It was known, however, that tungsten

lamps could be run at an efficiency as high as 0.20 watt per candle for a few seconds. The melting point of the filament prevented any further increase of the effiat 0.5 watt per candle the buils blackened hadiy within a couple of hours. The blackening of the bulb was thus the chief cause which prevented the running of tungsten lamps at very high efficiencies. Continuing, the G moral Electric Re-

Continuing, the General Electric Recition tative;

"There were the most diverse opinions store;

"There were the most diverse opinions store;

"There were most the most diverse opinions store that the life might be a sealy improved if a perfect vasuance of the property of the property

The action of water vapor was, there the water value attacked the filament producing a volatile oxide of tungeten and atomic hydrogen. The oxide that thus collected on the bulb was then reduced by the atomic hydrogen. The deposit was thus changed to a black layer of metallic tungsten while the hydrogen consisted with the oxygen to form water which again acted on the filament. The action of water vaner was thus a cyclic process by which large amounts of tungst be carried from the filament to the bulb

by very small quantities of water.

Efforts were then made to study the relation between the amount of water vapor on the bulb and the rate of blackening by this cause. Pressures of water vapor even as low as 0.0001 millimeter were aven as low as 0.0001 inillimeter were large and the series attest lighting on from 6 fp positione very rapid blackspring. As an apresent of a classic of a variety of the removal of water vapor, it was of high proven that the blackspring of bulks with color is respect to the removal of water vapor, it was of high proven that the blackspring of bulks with color is respect to the province of the series of t

probably due to ordinary evapora

probably due to ordinary evaporation.

"To set this theory, quantitative appearance have been made to determine the safe of loss of wight of tongene filaments in recouns when run at various temperatures. This work has conclusively above that the cause of the blackening of ordinary well-made than their rated efficiency; is supple wapparation. On the other hand, the rapid blackening of poorly made lamps is doe largely to the presence of water vapor.

The blackening of the largely made and the vaporation, the problem of improving the efficiency assumed more desilter form. To large the state of vaporations would have to be decreased or the evaporation will be a supplementation to the evaporation of the

From the foregoing considerations it is clear that the larger the diameter of the helix the higher the efficiency that may be obtained. The diameter of the helix is ordinarily limited by the sagging which is apt to occur if the mandrel or which the helix is wound is too large in proportion to the size of the wire.

With helically wound filements in nitro gen very high efficiencies can be obtained and yet the life of the flament may be and yet the life of the nament may be more than 1,000 hours. The blackening of the builb is avoided; and in properly designed buils the tungsten that evapor-ates produces only a slight brownish deposit in the upper part of the bulb, where it does no harm. A number of types of nitrogen-filled lamps have been made tested. Among these the most intere for the present are perhaps the following

"1. Large units of very high efficiency. (0,4-0.5 watt per candle with a life of 1,000 hours or more.) These take currents of at least 30-30 amperes and (except to units over 4,000 candle-power) are therefore best run from alternating current circuits by means of

from alternating currout circuits by means an annual transformers giving a rottage depting on the size of unit desired.

"3. Smaller ments of low cellage. "The currouts of the annures or less, at vage, in some cases, as low as four or, wets. The efficiencies with 1,000 hours with 1,000 hours are shaped for the currout used. The impa are adapted for series street lighting are adapted for series street lighting decreases an order of the currout of the cu

### How Much Do You Know About the Springs that are Under Your Car?

Do You Specify the Springs As Carefully As You Select The Tires, The Axles, The Magneto?

Perhaps you have never fully realised that it is not so much cushions, one with some month-rolling wheels, under your car, as it is springer. That it is the springer, far more than lies or bearings, that sheld the motor mechanism from road joils and jars—that case a car over the bumps and themps of bad going; thus saving depreciations and repairs.

### "Unhurriedly" Made By the Slow, Scientific Petroit Process

Forty-eight separate processes are used in the building of each Detroit Spring.

Porty-sight separate processes are used in the building of each Denroil Spring.

The basis of Detroit Spring super-quality is steel fabricated in an electric turnace according to fugruists based on tests by D. S. P. engineers and chemists. It comes to us in heavy tunnage lots, is carefully analysed to meet our own formulas, and is not allowed to vary in analysed to meet our own formulas, and is not allowed to vary in the process of the p

### The Spring Without a Squeak

A new patented feature of Detroit Springs is the Self-Lubri-caling Device. This revolutionaling feature consists of a distributing enables the leaves to softly, silently silfe one over the other with every movement of the spring, producing a velvety resilience not to be found in any other spring. Because of the patented device the day of squeak-

### A Scotch Manufacturers' View of American Industrial Conditions

IN the Western Supplement and Advertiser of the Scotsman for August 16th appears a letter from Mr. John Muir. eather manufacturer of Helth, in which he presents a very interesting picture of American industrial conditions as he found them during a recent visit to the Hultad States "In the vast corn belt where the chi

product costs about 25 cents a bushel to the farmers," says Mr. Muir, "they have had an unlimited market at over 50 cents, and are now realising up to \$1 a bushe for it in the form of hogs, owing to the high price of bacon.

"With the scope there in developing a new country and with well-remunerated effort, population has naturally increased till that of the United States to-day is ble that of Great Britain.

"Manufacturing enterprise has been stimulated by this agricultural and get eral prosperity till the exports of the United States have for the first time exceeded those of Great Britain this year.

"The Americans are a nation of chanics organised by men who know hos enamics organised by men was know now to get and how to keep business. Backed up by nature as their powerful ally and an ever-expanding home market, they are able and willing to now rapidly capture export trade. They turn out 65 to 70 pe

cent of the world's motor cars already.

"In Canada where a preference duty of
60 per cent is given to British makers, the Americans have already capture the Americans nave aireacy captured that market. A British car is rarely to be met with. Yankee enterprise is thus circling the globe, and it looks to me as if they intended that we should be left only with a congenial atmosphere in which to congregate around the parish pump to 'wait and see' them in full posusion of the export trade in that is

### The Race for the Gordon Bennett Cup By John Jay Ide, Special Aeronautic Corresp of the Scientific American

If Is eight clock in the morning at the Gare de l'Est,
Paris, on Monday, September 29th. An enormous
crowd is rushing for the train to coursy them to Rheims
in time to assist at the race for the Gordon Bennett
Cap. The railway carriages are completely filled by
standees who endure the two hours journey without a
murnaur. At Rheims we make a dash for the train
marked "Hacrdorme." It pulls out after shout a dosen
if us have clambered aboard, leaving the rest of the
trainful on the Butstrom. trainful on the platform.

As we approach the flying ground we see young Crom-bes, the Belgian representative who had drawn the first departure, circling the course. He started at ten o'clock. Although his Deperdusain is equipped with a 100 horse-power Gnome, he is not a likely

winner as he plays very safe at the cor-ners. His time for the 200 kilometers (124 miles) is announced as 1 hour 0 min-utes 52 seconds, whereat the Frenchmen feel perfectly safe.

Early this morning, several hours before our arrival, Emile Védrines made a trial circuit with his 160 horse-power Ponnier. inutes 58 seconds, which is over seconds better than Prevost's time eleven soconds botter than Prevoté's time in the eliminatories. On bearing this the Deperdussin manager became desperate and sent to the factory for new wings for Prevoté's mount. These wings, which would support the machine only in ideal weather, such as we are having to day, are almost perfectly flat on the under-side and have a span of less than twenty

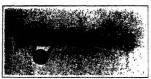

soon for Prevent to start at 11:15. The

soon for Prevont to start at 11:15. The powerful Galome syntage, into action at the very first averag of the tractor and Prevont deaders are to treat the stage when until he speeds up to eightly makes an hour. The flight as seen from the inning prior is impressed up the startess. He files very low, about strip foot above the ground, but before reaching the pytion he rises to \$5 test, buthat steeply, and, dives around the corner, fairly sharing the pytion. When the times amounted that Preventh has completed 100 kiloseters in 29 minutes 40 seconds, girling a speed four few 200 kiloseters now hear, we get greatly and kinometers in 29 minutes 60 seconds, giring a speed of jout few? 50 kilosusters per heart, we get greatly excited shal speculate as to whather the 500 kilosusters will be secondarised within the feser. As the two-risks lags, is completed our hopes two resident, as the risks lags, is completed our hopes two resident, as the risks in a secondarised our hopes two resident, as the single of 100 kilosusters per hour (126,5 miles per limited at 350,608 kilosusters per hour (126,5 miles per

Prevost, the winner, in flight.

A shout goes up for Bechereau, the brilliant and successful designer of the wonderful and justly celebrated Deperdussin monoplane. Meanwhile Cilbert starts in a Deperdussin, but with a greater wing spread and another make of motor- i.e Rhône. This ngine has all valves mechanically operated and uses oline than the Grôme, though of the same horse power (160) Owing to the greater prestige of the production of the Brothers Seguin, Le Rhône is very seldom chosen by pilots. Gilbert takes over three minutes for his first round, so is seen to have no chance to wrest the cup from Prevost. The crowd adjourns to

wreet the cup from revous. The crown unjoins to the restaurant, which does a roaring business serving a very poor lunch at ten francs a plate. On Gilbert completing the 200 kilometers Emile Voltnies starts on the all but hopeless task of beating Prevout's time. He is three seconds per lap slower Prevost's time. He is three seconds per iap slower than Prevost. If the Ponnier pliot had started first,

A new type of Morane-Saulnier driven by Garros.

wever, he would have held the world's record if only for an hour, as he easily surpasses the times set up by Prevost on Saturday. With Védrines' descent comes to a close the last free for all Gordon Bennett Cup we

shall probably ever see.

Below are tabulated the figures relating to the cup:

### Enforcing the Migratory Bird Regulations

FOLLOWING the proclamation of the President of the United States establishing regulations for the protection of migratory birds, the Department of Agri-culture has set in motion machinery to make these regu-

lations effective in every State on No nations effective in every state on No-vember 1st, the date set for the op-eration of the proclamation. These regulations put under Federal protection, for the first lime, a large number of migratory game and inscetivorous hirds and time place Federal restrictions on the five million hunters of the United Stafes, in enforcing these regulations Federal authorities will co-operate with State game commissioners and other State authorities in carrying out the provisions of the law and to prevent complications in the local enforcement of the regulations

Among the hirds protected by the regulations are the brant, wild duck, goose, swan, cranes of various species, rail sev-eral kinds of shore birds, pigeon, dove. wild pigeon, bobolink, cathird, chickadee, cuckoo, flicker, flycatcher, grosbeak, humming bird, kinglet, martin, mendow lark night hawk, nuthatch, orlole, roble sbrike. swallow, swift, thrush, warbler, whip-

poorwill, woodpecker, and wren.

Curious Self-Starting Accidents. - Of late examples are been seen of a disconcerting class of automobile cident which consists in the self-starting of the motor The most recent one of the kind occurred upon the route from Chemnitz to Buchholz, near Berlin. An autobus fell over an embankment and 27 persons were wounded motor had suddenly stopped when on the and the driver descended in order to start it up. Moan-while the motor started again and the autobus ran over the bank and fell for six feet. An accident of the same kind happened in Paris, where the automobile had been left for a short time with two children in it The motor started up and the automobile ran into the Seine, where it was entirely submerged, vith resulting loss of life.

### The Peril of Fire at Sea

THE two principal risks to which these who travel by sen are exposed are foundering and "Titanic" proved that, even in these days of tighty developed ship construction, the first of these risks was ever present and might be attended with appaling con-sequences. To-day the burning of the "Volturno" re--an ever-present menace in ocean miuds us that fire travel-may occur at any moment, and may be attended

with enormous loss of life
The lesson of the "Titanic" disaster has been laid well to heart; and it is realized that, as far as is me chanically possible, every ship should be made its own lifeboat and should be built with such complete subdivision that its foundering at sea will be a very remote contingency. The lifeboat of the future must be a larger and more seaworthy cruft, propelled by motors and comble of reaching the nearest rescuing steamship

But now comes the tragedy of the "Volturno" with its imperative demand that a searching investigation is made of the question of fire prevention and control on ships at sea. At the time of the loss of the "Titunic," says at sec. At the time of the loss of the Thanks, the Schwitzer Amsara wired that in the investigation of the question of safety at sea, the subject of fire risk should be given full condeteration. This winter there will be held in London a great international gathering of experts to determine the best methods to prevent the repetition of such a disaster as happene to the "Titunic," and the burning of the "Voiturno emphasizes the necessity for giving the deliberations of that gathering the broadest possible scope by including the subject of fire protection.

carefully compiled governmental statistics of such fires, great and little, as occur on ships at sea were periodically published, the public would be amazed to learn how many and how serious the fires are. The passenger steamship companies are well aware of the imminence and seriousness of this risk, and the speed with which such fires as do occur in the pass odations of ocean liners are detected and puout, reflects great credit upon the watchfulness and efficiency of the officers and crews. It should never be forgotten that the long reach of passenger accommodations, piled up as they are, deck above deck, and tilled with highly inflammable materials, calls for special provision against sorend of fire in the way of steel hulkhends, carried clear across the ship from side to side and extending to the topmost deck. These fire bulkheads should be provided with effective fire doors wherever they are intersected by the alleyways, and fire drills, with every member of the crew at his station, should be regularly carried out. Each fire compartment as thus divided off should be provided with its wa independent fire hose connections, and these be numerous, well distributed and of large capacity.

It is not the small first in the passenger accommoda-tions, however, which grow to serious proportions; the fires that endanger the ship, such as this that broke out on the "Voltarno," originate below deck, and asnaily in the hold or in the coal bunkers. Such fires as the recent outbreak on the "Imperator" are difficult to get at, and exceedingly difficult to put out. A coal bunker fire is proverbially stubborn and persistent, and an officer of the Navy has recently told us that in this service, even the long-continued filling of an entirely closed bunker compartment with steam has more than once failed to subdue a fire therein. A fire in the hold of the ship, particularly if it is flied, as in the case of the "Volturno," with highly combustible material, pre-sents an even more puzzling problem; for it is more difficult to exclude the air from a hold than from a

Why is it that the automatic sprinkler, which h proved so highly efficient ashore, has not been applied to the protection of ships? Structurally considered, the m should not be a difficult one, since the sys might be pisced inconspicuously in the cabins, alley might be piaced mensiprousny in the cause, and, ways, and sations, and the piping, fraes, etc., being overhead, would not interfere with the loading and un-loading of the various holds. An abundance of water supply under high pressure is always available aboard a stoumship, and the piping could be made of such generous capacity, that the putting out of an incipient blaze, even in a hold stored with inflammable material, may be rendered a practical certainty.

Two conspicuous lessons are that wireless has again

established its priceless value as a means of saving life at sea, and that the present lifeboat must be abanlife at see, and that the present increase must be assu-dened and a new type of large, seaworth, power-pro-pelled boat must be substituted in its place, and pro-vided with inunching mechanism powerful enough so-of sufficiently wide reach to place these larger lifeboats ea, well away from the ship, and clear of any risk of being wrecked by collision with the same "Grosser Kurfuerst" seems to have used a power boat which did noble service in a sea in which oar-propelled lifeboats were comparatively powerless

#### To Beautify the Panama Canal

HE National Commission of Fine Arts, through its chairman, Daniel C. Freuch, has placed before the Government its views on the question of beautifying the Panama Caual. Congress in August, 1912, authorized the Commission to report its recommendations regarding the artistic character of the struc tures of the cannil, etc., and into this question the Commission has entered very thoroughly and with con-clusions which reveal a correct judgment of the situa-

"The canal," says Mr. French, "like the Pyramids, or some imposing object in natural scenery, is impress from its scale and simplicity and directness. One fe that anything done merely for the purpose of beautifying it would not only fall to accomplish that purpose, but would be an impertinence"

earing in mind the character of the Comm may be said that the above conclusion was inevitable, for it is certain that even the cansal visitor to the canal, if he be possessed of any artistic sense, or sense of the fitness of things, must realize that the adornment of the canal on any extensive scale is an utter impossibility. The shoreward view as one enters from the Atlantic is firt and uninteresting, and presents no natural feature which invites the erection of any ade quate monumental structure. The fine two-mile break water extending from Toro Point terminates in a light house for which the Commission has made some after native plans that have been adopted. It is proposed that if suitable foundations can be developed, a monu nental lighthouse should be built where channel through the lay commences, or else that a lighthouse be located near the position marked by beacon lights 1 and 2 1f this is impracticable, it is recommended that a lighthouse or some form of mo ment be constructed on the first high solid ground countered in entering the canal from the Atlantic, say at the Mindi Hills where the Gatun locks first attract attention. Unless this structure be built on a scale commensurate with the magnitude of the canal, we think it had better be omitted altogether.

Although the Commission felt that it was desirable to mark the entrance to the caual from the Pacific in a manner similar to that proposed for the Atlantic end was found that the conditions were not favorable to It was found that the conditions were not already as such a structure, and it considers that nature has pro-vided in the shore line itself, with its rugged range of mountains, and in the interesting islands guarding the cutrance, an approach which is sufficiently im

The most practical suggestion, one which we believe will meet with general approval, is that for the construction of a vast memorial tablet in the Culebra cut. It is proposed to form an impressive inscription upon onumental surface at some point of promia great monumental surface at some point of promi-nence, and preferably on the east wall of the cut at the point of the deepest cut—482 feet—where the canal passes through the Continental Divide. The Commissuggests that the tablet should be approximately 100 feet in height, and somewhat more in width; that it should be severely simple in design, and that the lettering should be done in Romau V-shaped letters, large enough to be easily read by normal eyes from the opposite side of the ennal. It is proposed that the material shall be concrete and applied as a mas facing to the trap rock of the cliff.

Now here is a suggestion W altogether appropriate; and we trust that who subject matter of the inscription comes to be deupon, care will be taken to make record of the that the successful carrying through af the great d of the fac was due to five years of continuous supervision by that capable and faithful officer, Col. D. D. Galliard, whose health was disastrously wrecked on the ere of the completion of the work.

#### What Have the Russians Discovered in the Arctic?

PRESS dispatch from St. Michael, Alaska, dated October 11th, announced the arrival at that port of the Russian government vessels "Taiand "Waigatch," just back from a summer cruise in the Arctic, in the course of which had been discovered a hitherto unknown land, vaguely described as "extending beyond latitude 81 north and longitude 108 st," and said to be "as large as Greenland." west, and said to be "as arge as Greenland." This information was somewhat modified in subsequent dis-patches. The newspaper accounts of the discovery, however, up to this writing, have persistently distorted its true character and importance, and it, theref

its true character and importance, and it, therefore, seems destrible to attempt a reconstruction of the story in the light of known facts.

The vessels in question, which are ice-breakers, were first assigned to Arctic work in the summer of 1911, when they were sent by the Russian government to execut the expedition of Admiral Trajan, on the "Kolyma," to the Arctic coast of Siberia tols Bering Strait, the week true head by the Processible (8c.) No. 1852/class." ma," to the Arcite const of neighbor between the many proceeding without them. The following summer they made another attempt, entered the Arcite Ocean, carried out important explorations and surveys as far west as the mouth of the Lens, and made an unsuccessful effort the mouth of the Lena, and made an unsuccessful enor-to pass the Talmyr Peninsula, in order to complete the Northeast Passage to Europe. Early last July they sailed from Vladivostok on the voyage which they have just completed. The last expedition was commanded by Major General Sergejcv, but he was forced by illness to leave the party in Bering Sea, and returned south on a Russian cruiser, leaving the com-mand to Lieut. Wilkitzky. When last previously heard from the ice-breakers were off the northern Siberian coast and were understood to be making another at-tempt to pass the Taimyr Peninsula. It was not anticiputed that they would try to reach the high latitudes which they appear to have attained.

According to later and more circumstantial reports the explorers were endeavoring to reach the n the Yenisel, but on account of ice along the coast the Yenisci, but on account or ice along the coast, turned north, and thus stimulated upon the new land, which they encountered about 00 miles north of Cape Chelyuskin. They cruised northwesterly along the mar-gin of the land to intitude 81, longitude 90, where a solid pack prevented further progress, though the land could still be seen extending to the northwest. In the opposite direction the const-line was followed to longi-tude 104, intitude 79, where it turns to the northeast. The land is mountainous, and gives evidence of recent The iand is mountanous, and gives evidence of recent volcanic activity. The explorers landed, raised the Russian flag, and took possession in the name of the Czar, maming the land "Nicholas Ii. Land." In all, about 200 miles of const-line appears to have been actually seen by the explorers—a very far cry indeed from the "Arctic continent" or "land as large as Greenland," of which the newspapers have been tell-

Reference to any one of the numerous mans of the Arctic regions on which is shown the route over which Nansen drifted in the "Fram," in 1803-96, will furnish convincing evidence that the newly discovered land must be of very small extent as compared with a conti-When the first report of the discovery was received it seemed possible that the longitude had been incorrectly reported, or that the explorers had reckened their longitude from Pulkova instead of Greenwic In either case the new coast might have been the border of a land mass of great extent, occupying the site of the hypothetical continent or archipelago required, ac-cording to Dr. R. A. Harris, to explain the Arctic tides, i. a., the terra iscoputa which the Crocker Land expedition is now seeking to attain from the south-east and the Canadian Arctic expedition from the south. This supposition was, however, dispelled by the definite atatement, in a later report, that the new land begins 60 miles north of Cape Cheiyuskin. It must therefore lie between the route of the "Fram" and the Siberian coast. Moreover, as Nansen obtained soundings of from 10,000 to 11,000 feet only two or three degrees north of the Russian discoveries, and found no evidence of land in that vicinity, Nicholas II. tound no evidence of land in that vicinity, Nicholas II. Land can hardly extend very far north of where it was estually seen by its discoverers, and can have no physical consection with, the extensive lands which, many geographers bolieve to exist north of Ataska, red, easternators (Bheria. The propositive lauren of fice-fanon, or MacMillan, or Amundeson—as the case may: be-are still safe.

#### Engineering

mittels Dreadmought fitrength.—According to the Blads and Milliany Record, by March 31st of next gair Greek Britain will have in commission 32 dreadwards and Germany will have 15. The Record notes the fact that for a short time at least, Greak Britain will have reached its desired standard of two ships to one in battleships of the dreadmought type.

The Jura Tunnel Commission.—

one in battleships of the dreadnought type.

The Jura Tunnel Completed.—The boring of the
Mont d'Or tunnel between Prance and Switserian,
which was commenced about three years ago, was
completed on October 10th, when the two gauge which
all been working from the Swits and the Preson is dies
met. The tunnel which is 3 3-4 miles in length pierce
the Jura mountains from Present to Vallorba, saving
thoreby a seven-mile detour by Pontarlier. The line
will be open for traffic early in 1914.

will be open for traffic early in 1914.

New Material for Automobile Reads.—Experimental tests giving satisfactory results have been made in France with a new road-surfacing material, which has been devised specially for automobile traffic. It consists of a mixture of what is called "iron straw," which consists of fine filaments of iron in a wiry or fibrous mass mixed with cement and easd. It is stated that the fron is not a waste product, but it is made by machines designed for the purpose.

A Boy-Secut Cantilever Bridge.—An effective cantilever bridge built by boy-scouts is illustrated in Engineering News. The bridge was built after a sixted made by Prof. D. B. Steinman of the University of Idaho. A24-foot suspended span consisting of two 6-lank logs passes into grooves beveled at the ends of the 8-lank logs forming the eastliever seria, the latter being kuried under a rock fill, in inclined hoise dug in the banks of the river. The roadway consists of cross logs held in place by longitudinal stringers.

place by longitudinal stringers.

Cost of the Panama Casal.—Up to date the Panama

Canal has cost \$314,370,978. The total cost when comploted will be within the criginal estimate of \$375,000,000.

Engineering has cost \$185,316,095, and of this nearity
\$44,000,000 has been spent on the Culebra cut. Sanita
tion—a fundamental necessity if the canal was ever to
be built—has cost \$16,250,104. The sale of old material,
the work done for outside companies, and water rentals

from Panama have yielded the United States about

A Difficult Bridge Problem.—The city of Caigary, Alberta, has recently solved a problem of bridge construction in a novel manner. The town lies on each side of the Bow River, that portion on the north bank being built on the high blidfe which border the river on an incline to the top of the blidf would have been to neglect the portion of the city lying at the foot of the bluff. To make a deep cutting would have spoiled mush of the property. The problem was solved by constructing a level bridge across the river, and then gaining the heights above by an inclined tunnel bored through the ciliffs.

British Fire-Director Gunney Record.—The British batteship 'Centurion' has made & fan record in its gunlayers, which may be compared with that of the windown of the property is correct, this is a very small target for the property is correct, this is a very small target for the property is correct, this is a very small target for the property of th

The Straits of Panama—The chief engineer of the Panama Canal Company when the work was in French hands, Philippe Bunau-Varilla, in a dispatch from Colon, states that the completion of the look casal mark the beginning of its transformation into a free strait at sea level. Varilla has always favored the construction of a sea-level conal by the hydratillo method. He proposed commencing at a summit level fed with water from the Chagres, and using hydraudic dredges, successive longer reaches enclosed by end dykes being filled with water as the depth of the out increased. The achence was not considered to be practicable by the lathwine Canal Commission.

The Canal, the Merchant Markes and the Navy—
that the American-Hawalian Lies has built and is
building night new vossio of all and seven thousand
building sight new vossio of all and seven thousand
tons for service through the Panama Canal, which will
bring the number or playe
age of 29, the number of playe
ton the seven through the Panama Canal, which will
be in 28, the number of playe
ton to the number of playe
ton 128, 500 to 28,000
tons to rour navy in oses of war. Other conseives
morance or sent anging their flaver, and the activity has
extended to the Great Lakes shippared; the whole outcome of which, as affecting the navy, will be that not
only will a fine fleet of colliers be available, but the
said salarged fleet will provide a body of men trained to the
said and shizable for salistment.

#### Science

Professor Friedrich Peckels, the well-known German physicist and editor of the Beblatter su den Annalen der Physik, died August 29th at the age of 58.

The Next Eugenics Congress.—It has been decided that the next international Engenics Congress will be held in New York in 1915, on or about September 20th.

The Northeast Passage.—The Russian loe-breakers "Taimyr" and "Waigatch" left Vladivostok early in July on a voyage size Bering Struit to the Arctic coast of Siberia. It is proposed to renew the attempt made by the same vessels last year to round the Taimyr peninsula and pass through the Sea of Kars to Europe.

Gasemsters as Aerial Signposta.—In accordance with a resolution adopted by a gas congress recently held at Toulouse, a number of gas companies in France have agreed to paint direction and geographical signs on the roofs of their gasemeters for the guidance of ascenauts. A numerical system of signs elaborated by the National Aerial League will be adopted.

Water Fower Development in Iceland.—A consular report states that an English company has just purchased Dettifalls, the largest waterfall in Iceland, situated about 35 miles from the seacoast, on the River Tokula. The company proposes to erect large works for producing festilizer from atmospheric nitrogen and to build a railway from the coast to the falls.

Cloth from Seaweed.—The much talked of English project of utilizing the fiber of a seaweed. Posidonic neutrale, se an admixture with wool in blankets, various kinds of sloth, and for the warp of carpots, appears to have come to grief. An order in Chancery was recently made for the compulsory winding up of the company engaged in exploiting this scheme. The embarrasament of the company is, however, reported to have been due to causes not militating against the feasibility of the process in question.

Use of the Camera for Judging Races.—An automatic photographic apparatus for judging races proved successful in Prance and will be used at the next Paris international race meeting. A camera is placed in line with the winning post, and the winning horse, by breaking a thread, releases the electrically controlled shutter and a photograph of the finish is taken A similar device was used at the last Olympic Games at Stochholm, but there the photographs were chefly used as additional evidence in case of a disagreement between the judges.

Vacant Let Gardens in our large cities represent a form of practical philanthropy that is attracting favorable attention throughout the country. In Philadelphia, according to the last annual report of the Philadelphia, according to the last annual report of the Philadelphia, according to the last annual report of the Philadelphia Vacant Lofs Cultivation Association, the land is lent free of charge by the owners. The association spends about \$45 a garden for plowing, fertilizer, sood, etc. Each garden is assigned to a family, which pays \$1 the rise cases, \$2 the second, and so on, until the fifth season, when about the full cost is collected. In 1912 42 families were assigned gardens, averaging about one sixth of an acre. The families spread the fertilizer, and plant, cultivate and harvest the crops, supplying their own tables and selling any surplus.

Interesting Work for Telescopists.—The American Association of Variable Star Observes has just completed its second year's work with a total of 12,900 observations to its credit as compared with 6,180 observations contributed last year. The association has a membership of twenty observers, and in under the direction of Prof. B. C. Prekering, Director of the Harvard College Observatory. The value of cooperative observing in this line of telescopic work has been fully demonstrated, and it is boped that more telescopies will join the ranks of the association. Here is a splendid opportunity for anyone with a telescope of three-ional sperture or larger to suggest in an interesting and practical line of solicitifies research. These interested are required to address William Tyler Olcots, Corresponding Scoretary, Nor-bib. Corus.

wich, Conn.

How the Government Tests Paper.—In the Scientific Amusican for October 4th, there appeared an article entitled "How the Government Tests Paper." Under the heading "Analyzing Londed Papers" there appeared the following statement: "The amount of sach thus obtained in really less than the sotual amount of loading or filler, which may contain water or other volatile agents that pass off in the burning." This statement requires explanation, as it takes no account of the natural sach the filters used or the saft from other raw naivestals. Except in the case of calcium sulphate fillers, the amount of water or volatile matter would not exceed five or ten per cent of the weight of the filter present. As the natural sach may be as high as 1.5 per cent of the weight of the paper, and in a sized paper is saidong, if war, less than 0.6 per cent, it is apparent that the statement given would create a false impression of unloaded or slightly loaded papers, where the sach is in excess of the amount of filter in the paper.

### Automobile

A Sectional Rim Spring Wheel.—August Gerleit of New York city has patented, No. 1,066,267, a vehicle wheel which has spring poloes and a rim composed of separate sections. The outer ends of the spokes are secured to the adjacent ends of their respectiver im sections. The connection between the spokes and the rim is a sliding one.

A Mowing Attachment for Motor Vehicles.—In patent No. 1,098,705 Otto Kluge of Golswafa, Ill, combines with an automobile flywheel a mowing device driven by a shaft operated from the flywheel of the automobile outcome, saitable controlling and supporting means being arranged in connection with the other parts of the apparatus.

Two Patents for Eye Protectora.—Gilbert D. George of St. Paul, Minn., has secured two patents Nov. 1,070,384 and 1,070,385, for eye protectors, in bolto of which two fiethle transparent shields are arranged to overlap and are pivoted together, and no ue patent the shields are concavo-convex so they may nest together when folded. When the shields are concavo-convex so they may nest together when folded. When the shields are opened out they precare of spectacles and are smillarly used

Special Roads for Automobiles—The increasing use of automobiles in Europe is leading to the construction of aspecial routes reserved occlusively for this class of traffic. One of the first of these to be built in Germany of extensive length is to run between Disseldorf and Dortmund, and it will have about 80 feet width throughout the whole length, according to the present project. As to the part of the route which traverses Westphalas, the several municipalities are now discussing the plans

Combination Lock for Sparking Circuit of Astomobile.

—Recent publications mention a combination took for
use in the sparking circuit of an automobile in which
a pushpin combination look is utilized in completing the
circuit. In 1904 Pay Leone Fauroi of Aim Arior, Mich.,
took out a patent, No. 759,000, for an apparatus, the
object of which was to provide a switch in the electric
circuit of an automobile which circuit could be completed
only by a predetermined definite arrangement of parts
not apparent to the observer. The part to be so arranged
were the elements of a combination look. Somewhat
similar devines have been provided in the patented aris
in which combination looks have been arranged in connection with the electric circuit and some of the valve,
in some instances the fuel valve of an automobile, in
such manner as simultaneously to control both the
circuit and the valve.

Usited States Leads in Motor Vehicles,—At the rocent International Road Congress ledt in London, a complete seems of the world's motor vehicles was compiled for the first time. As the United States leads in the production of sutomobiles, so she also leads in their operation. It was learned that this country possesses more than half of all the motor vehicles in their operation. It was learned that thes country possesses more than half of all the motor evels, their gibbs, is as compared with England's 125,728. The baliance of a total of 1,161,911 as distributed throughout the other countries of the world. France ranked third with 89,185, and Germany fourth with 70,003. The total number of motor trucks, included in the above figures, is given as 69,055. Usually the number of automobiles in any country greatly exceeds the number of trucks, and only 15,518 pleasure cars. It should be noted, however, that these figures are based on reports dated June 1st, 1912, and probably fall far short of the set all number of vehicles in use to-day It is estimated that there were no less than 300,000 motor vehicles must contain the torter were no less than 300,000 motor vehicles must contain the torter were no less than 500,000 motor vehicles must contain the torter were no less than 500,000 motor vehicles must contain the country of the set as the contained that there were no less than 500,000 motor vehicles must contain the country of the set as the contained that there were no less than 500,000 motor vehicles must contain the country of the set as the country of the s

A Find Steel Ring Shock Absorber.— It is estimated that unward of \$20,000,000 a year is being spent by motor truck users in this country for repairs and replacements, caused chiefly by road shocks. The permanent access of the whole motor industry depends, in no small measure, upon overcoming this greatest country to the progress and position. In a former sense we are the properties of th

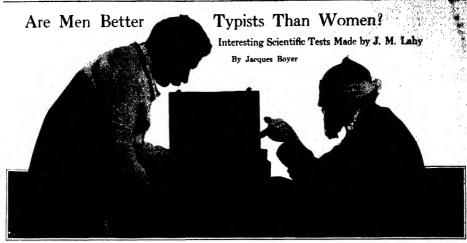

Fig. 1.-Measuring the muscular sensibility with the myo-esthesimeter.

WillAT are the aptitudes essential to success in the type-writing profession? How can these upitudes be defined and measured scientifically? Are men superior to women in the operation of the writing machine? M. Lahy has endeavored to solve these psychological problems, and although like experiments have not yet been carried far enough to allow a definite conclusion

to be stated, they possess an unquestionable social interest In particular, they prove that slow action, perfectly adapted to its purpose, is more effective than rapid but illco-or d in a ted movements, and also that the sensorial reactions of typists are different in the two sexes

From the numerous subjects examined by M. Lahy eleven persons, varying in agreement from twenty to thirty years, we re selectly conjurable. Six of these were women, who had had from two to four years' practice. In ypowriting, and five were mon, whose experience ranged from two to they work or eight years.

In order to effect this classification, the typists were required to typewrite an ordinary text containing 1,702 letters and figures, and their copies were submitted to the judgment of an expert typist After this preliminary test M. Laby dividual, the tactile sense of pressure with ity with the myoesthesimeter, the nudi-tory reaction-time with the d'Arsonval chronoscope, and the muscular strength of each band with the Régnier-Chéron dyna-mometer. He also examined, by means of appropriate tests, the memory for letters and

phrases, the attention and some higher intellectual faculties, including imagination, abstraction, judgment and reasoning.

I will now describe briefly the construction and opertion of the instruments mentioned above.

The haphi-esthesimatric compass of Weber, improved by Toulouse and Pieron (Fig. 3) consists essentially of two fine needles attached to no oscillating lever. The distance between the points of the needles is varied and measured by means of a graduated slide provided with a knob. The operator, holding the compass by its asked applies it to the closed hand of the blindfolded subject so that the two needles exert equal pressures. He then notes the ministum distance to which the needles must

be separated in order to give the impression of two distinct con-

### Airbine Reduction Gear in Relation to Battleship Fighting Power

### How Light Reduction Gear Turbines Would Add Two Fourteen-inch Guns to the "Nevada"

ECADEAT exteed, the guiding principle in the dealer A of a battleship is to obtain the mardanum amount of fighting power upon a given displacement, that is to say, the total weight of the ship and her equipment when she is afond, is the capital which the architect has to draw upon in genting out the plans for his ship. Thus, in the case let us say of the "Nevada," a ship of 27% and the "Nevada," a ship of 27% and the "Nevada," a

the "Newada," a ship of 27,500 tons displacement, so much to the displacement is devoted to the displacement is devoted to the hull, so much to the number of the number of the stream and the number of the superdomment of weights to these different requirements, we have in the "Newada" a ship 575 feet long, 575 feet long, 575 the tong, 575 feet long, 575 the tong the superdomment of 25.5 knots, and carrying a biterport tent 1-times pum a biter of tent 1-times pum. It is the superdomment in the various elements of the ship which results in what we believe to be the most decenter bettleship of her displacement in the world to-day.

Bome other naval architect, bowwer, realizing that he had the great displacement of 27,500 tons at his disposal, might have decided that such a ship should carry a heavier battery and he might have designed one of the same sise, mounting twelve in place of ten 14-inch guns. But in doing so he would have been obliged to, sacrifice some other valuable feature in her design.

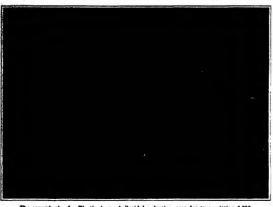

He would have found it necessary, let us say, to reduce the thickness of the armor to that of a battlecrutuer, or it would have been necessary to reduce the amount of coal carried and give to the ship a less generous amount of ammunition and etores; in short, he would have been obliged in some one, or in several ways, to servifice certain features which make the "Nevrada" used a fine all-round fighting unit.

One of the largest drafts made upon the displacement capital of a warship is that for the boilers, eugines and fuel supply; and for many years it has been

realized that, if some change of motive power, or some radical change in existing met could be made involving a reduction in weights. it might be possible, on the same displacement, to produce a ship of greatly increased fighting pearance as a practicable drive, it was predicted that its high efficiency and decreased weight would render this possible; but that these expectations have not been realized is shown by the fact that the "Oklahoma," sister ship to the "Nevada," and of the same displacement and armor protection, is being equipped with triple-expansion, reciprocating engines. It was hoped that the heavy-oil engine of the Dissel type would make possible the desired reduction in weight; but at the present writing It is agreed among the most experienced builders of oil engines, that there is little hope of this type of drive being installed in battleships for many years to come. During the past few years however, there has been brought to perfection an adjunct of the steam turbine which promises to enable that most efficient engine to ises to enable that most success. Successful demonstrate its full economy, both in weight and in fuel consumption, as a drive for ressents of the navy and merchant marine. We refer reduction gear, a device which makes it possible to combine the most economical type of

possible to combine the most economical type of a invitine with the most economical type of propeller in any given ship. The difficulty with the marine invitine is a fundamental cone. It lies is the impossibility of reconciling the high speed of rotation necessary to secure high difficulty in the truthen with the low speed of rotation which is necessary to secure high self-culvey in the proposite. If the truthen is run at the marinium efficiency speed, there is a great loss of efficiency in the propolate; if the propolate is run at the own marinium efficiency speed, there he a consumption, of sheams in the truthine out of all proportion is the proper distincted.—A A high parapheral velocity is

necessary for the turkine blades, if they are to utilise the energy of the stems efficiently, and hence if the speed of rotation is limited, the desired peripheral speed dots he secured only by an increase in the diameter of the rotor. This brings with it the disadvantage that the turbines become objectionably large, and heavy to handle during inspection and repairs. Furthermore,

The apurwheels of a Westinghouse helicoidal reduction gear for transmitting 6,000 horse-power at the station of the Cleveland Electric Illuminating Company. Efficiency in sheep test ever 95 per cent.

the large casings necessary in turbines of great power, are liable to expand unevenly when the steam is first somitted. This is liable to bring them in contact with the blades, whose clearances are necessarily very small, strip them from the rotor and necessitate the return of the orthogonal ship to the navy yard.

During the past few years, a large amount of costly experimental work has been done in the endeavor to introduce between engine and propeller some form of reduction gear, by which the high speed of the turbine shaft could be reduced to the relatively low speed of

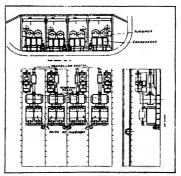

Diagram showing saving of space by using mechanical reduction gear with high-speed turbines in the engine room of a 20,000-ton battleship. Saving of weight is 400 tons.

the propeller shaft, without any serious loss of efficiency. These efforts have resulted in the production of three types: I, the electrical, in which a high speed turbles is direct connected to a generator, current from which drives a motor direct connected to the propeller; II, the hydraulic typs, which introduces between the power and the propeller shaft a reduction great, which may be broadly defined as a centurical pump and a water wheel; III, a straight mechanical gear, consisting of a pinion on the power shaft gearing with a spur wheel on the propeller shaft. Type my the propeller shaft.

number one, for which an efficiency of 80 to 05 per count is claimed, has been instalted on the United States collier "Jupiter." Type number two, which has shown an efficiency of 90 per cent in a brake test of 10,000 norse-power, is being installed on a large scale in a German merchant ship. Type number three, of which the Westinghouse-MacAlpine reduction gear is the best

known type, has been placed in the collier "Neptune," of 19,300 tons displacement and It knots speed, in which it has shown the same mechanical efficiency of 98 per cent as was reveated by the preliminary shop tests Parsons, of turbine fame, has made some smailer installations on this principle, in high-speed passenger boats, which appear to be giving good satisfaction. At the ores ent time, moreover, there land service 22 sets of Westinghouse gearing with an aggregate horse-power of about 20,500, and present an illustration of one of two sets of 6,000 horse-power which are now in service at the station of the Cieveland illuminating Company Fifty-four addlional sets of gears, having an aggregate horse-power of 67,000 horse-power, are under construc-

The distinctive feature of the Westinghouse gear which, as can be seen from the Hustantions, is of the double helicoidal type, is that the platon shaft and hearings are supported hydraulically in such a manner that there is an automatic equalization and distribution of the tooth pressure. This effect is secured by locating an hydraulic

sure. This effect is secured by locating an hydraulic epilheder and piston under each of the three pinion shaft bearings, which are held in a common frame The lubricating oil enters the bearing at the region of low pressure and is carried around to the region of high pressure, where a portion of it is discharged through an opening leading to the hydraulic cylinder Under this arrangement, the frame in which the pinion shaft is carried floats upon the oil contained in the hydraulic cylinder, and, since the pressure in these is paramitted to equalite, there is a resulting automatic all these of the pressure in these is paramitted to equalite, there is a resulting automatic all these of the property of the proper

alignment of the philon teeth with those of the main gear, and there is consequently a uniform distribution of tooth pressure. The smoothness and entire absence of noise suggests that a custtoning effect is obtained by a small amount of entrained air which amplifies the effect of the floating bearing

moture nearing. Tests which were made at the Westinghouse shaps with a turbine of a capacity of 1,000 kilostati, at 3,000 revolutions per minute, broacht out the very important facet for many the broacht of the property of the property of the property of the property of the range of power, and with no squared diminution at the highest power attailed, and this in squite of the facet that the turbine was being operated at double its ratted capacity. In fact, the tabulated results showed that, as the flow of steam was increased, the water rate was reduced. This reduction, moreover, was tabulated to the fact that the flow of steam was increased, the vater rate was reduced. This reduction, moreover, we want to the property of the

Important as are the galas in efficience, they are, if possible, overslandowed, particularly for naval insuliation, by the great saving which may be secured in weight and space, the effect of which in increasing the fighting power of a battleship without increasing its displacement is referred to later in this article.

The principal mechanical and operating advantages of this drive which have recommended it so strong to naval engineers are: One, that tight steam pressures may be used with superirest and that the turbine may be started quickly from the cold condition without danger of casing distortion and binde stripping. Two. the smaller size certaint but turbine casing to be made

in two parts, with the elimination of circumferential toints and reduced cost of manufacture. shorter and lighter rotor makes possible the use of a sliffer shaft and the practical elimination of vibration with its consequent blade trouble. Four, the upper half of the cashig may be bluged and the turbine rendily opened for inspection. Five, the very great reduction in the number of blades greatly lessens the danger of blade stripping. Six, the smaller size of the turbine makes it possible to place the condenser directly bemeans it possure to place the condensor directly be-neath it—thereby securing a inhiminum loss of pressure and eliminating the large and cumbersome exhaust pipe —and use the shell of the condensor as a foundation for the turbine

What Reduction Gear Would do for the "Nevada." By way of illustrating the advantages in the way of space and weight saving and the more convenient size of the parts to be handled to repairs and overhauling we present the accompanying tabular comparison and some diagrams showing eight small turbines geared in pairs to each of the four propeller shafts. The com-parison speaks for itself; but we cannol refrain from drawing attention to the reduction of 50 per cent in the weight of turbine, to the fact that the weight of the weight of turning to the fact that the weight of the largest rotor is reduced from 30 tons to 1.8 tons, that of the largest turbine complete from 120 to 11.1 tons, and that of the largest piece of turbine from 30 to 4 tons. Furthermore, it should be noted that the reduction of 13 per cent in the total steam used will mean a further reduction in the weight of the botter plant and in the weight of coal carried for the same cruising radius

A Twelve-gun "Nevada."

Now the reduction in the boiler plant and accessories due to the 13 per cent saving in steam used, would ut a very conservative estimate service un additional say ing of 50 tons of weight, which, added to the in turbine weight, means a total saving of 350 tons in molive power nione. And this, the naval architects will tell you, means that there will be about an equal amount of weight saved in the ship itself, making a total saving by the introduction of the reduction gear of some 700 tons. This, in turn, means that the iwo 2-gan turrets of the "Nevada" could be increased to 3-rm; furrets, and thus we would secure an improved ada" of only 27.500 tons, carrying twelve 14-luch, which is the battery that will be mounted on the 31,500-ton "Pennsylvania."

The ten-gun "Nevada" costs about twelve million five

hundred thousand dollars. The twelve-gun "Pennsyl-vania" costs about fifteen million dollars. The extra valua" costs about fifteen million dollars. The extra two gaus and larger tirrive to a reducibin goar driven "Nevada" would fairly well offset the saving in welght of molive power if this be true, a twelve-gau relation "Nevada" with reduction gears could be built for \$2; 000000 loss cost tani a twelve-gau "Pennylvania" without reducion gears; which would mean that it would be possible to intill six twelve-gau. "Nevadas"

for the same cost as live levelve-gun "Pennsylvanias."
This article is not intended as a criticism of the design of the "Pennsylvania" The increase of 4,000 tons over the "Nevadal" covers not merely the additional two gams and their mounting, but many features, pre sumably, in the way of better protection, larger fuel supply etc. We merely wish to point out that the "Nevada," the most completely armored ship in the world, can be made to carry two additional 14-inch gams by a mere redesign of her motive power

by a mere reassign of her notice pawer.
We commend these facts to the serious consideration
of the Bureau of Construction and Repair and that of
Steam Engineering when they come to prepare the plans for the three new buttleships which the Secretary of the Navy will recommend to Congress.

### New York Electrical Show

Tile New York Electrical Exposition and Motor Show of 1013 opened at the Grand Central Palace, Wednesday, October 15th, and will couldnue until Saturday, the 25th, inclusive

The exhibition is well supported by the Federal Government. The Department of Agriculture illustrates

with pictures, models, and maps what the Govern is doing toward the protection of our forests. There is an erosion model which shows the effect of streams on denucled land as against well-forested country. The methods of signaling and fire fighting form an inter-esting part of this exhibit. The Department of Comand Labor illustrates how statistics are tabulated by the Bureau of Census with electrically ope meet of the Bureau of Census with electricity oper-uted punching and sorting mechines that take card re-ords at the rate of 450 a minute. Another popular exhibit of this despartment is a model of the Pedro Miguel lock of the Panama Canal. The model, 20 feet long and 5 feet wide, shows the actual operation of resulty least from one lead to the actual. passing loats from one level to the oth partment of the Interior is represented by a model of an authracite coal mine in operation, and shows how in the modern mine nearly everything is done by elec-tricity. The attention given by the Government to units and measures of electrical quantities is demonstrated in the exhibit of the Bureau of Standards; while the Reclamation Service shows what is being while the accumulation service shows and is being done in the West in the development of water power for the generation of electricity. In one corner of the building there is a fully equipped mint showing the process of manufacturing coin from the crude material to the flusi stamping press. The United States Navy is represented at the exhibition by the bridge of a battleship in regular working order, which demonstrates the electric signaling devices used on our war ve In addition to this, deep-sea sounding apparatus and in addition to this, declines councing apparatus and pavigating instruments are shown. Field wireless and time firing apparatus for coast defense guns form the interesting features of the United States Army exhibit. In addition to the Federal exhibitions there is a State

exhibit of model locks and spillways on the Barge Canal, while the Bureau of Municipal Research also shows how the affairs of New York city are now being

One of the special features of the present show is One of the special returns of the present show is the purt that electricity is now playing in medical mat-ters. The section devoted to electro-therapeutics com-prises more than a dozen separate exhibits. One of these consists of a model hospital, where every concelvable form of electrical apparatus has been installed for the benefit of the patient and the surgeon. There are high-tension machines, galvanic machines, sinusoi dal muchines, machines for ultra-violet light treatment, dal machines, macmines no untre-vance man coemisco. X-ray machines, electric ficultators, beth cabinets, elec-rically heated blankets, etc. Particular stress is laid upon the use of Roenigon rays in locating trouble in various parts of the body. In this electrical hospital may be seen a large electro-magnet with which iron and steel particles may readily be removed from the eye or from the skin.

As usual, the growing use of electricity in the b hold holds a prominent position in the exhibit are the customary devices for cooking, cleaning, washing, etc., which have now become standardized and show only minor improvement over those exhibited in previous years. At one side of the second floor is the electrical grill and ten room where electrically cooked meals are served. One electric power company demon-strates what can be done to the equipment of a build-ing for electric lights, including all the fixtures, on an expenditure of \$60. Another company advertises to fit up any city house within its area of operations for \$49. This company also shows what can be done for 10 cents by the use of various electrical apparatus and

On the top floor of the exhibition hall there is an etectrical farm and dairy. Four white cows are daily milked by electricity. The method of clarifying the milk, separating it, pasteurizing the cream and cl milk, separating it, pasteurizing the cream and churning il into butter, all by means of electrical apperatus, is here shown. The farm also includes a poultry yard and chicken hatcheries where baby ducks and chicks are hatched during the exhibition.

illuminating engineering is well represented by vari-ous types of imps. Special attention is shown to the reproduction of daylight by which colors may be matched. To demonstrate the ruggedness of tangeten lamps a bumping device is used which subjects the lamp

to severe jars without injusting the disment. The nitrogen-filled lamp will probably be on exhibite fore the show is over. This base, as our redders i will operate with very high efficiency, consuming 1/2 watt per candle-power against 1 to 11/2 watts of present tungsten lamps.

The motor truck is well represented by any number of exhibits which demonstrate the increasing use of the electrical commercial vehicle in the city and in places where electric current is readily available. At the top floor of the exhibition, there is a demonstration track and an electrical garage, completely equipped with battery charging apparatus, demonstrating the simplicity of the charging operation.

### The Destruction of the Zeppelin Airship "L II"

S we go to press news is received of the terrible dis-A steer in which the new Zeppelin naval airship
"L. II." was totally destroyed. It is said that the versel exploded in midair and that every one of the twenty-eight officers and men on board lost his life. Among those who were killed were members of the Admiratity Board, who were testing the airship before accepting her for the government. It would be both unwise and un-safe to venture any discussion of this, the most frightful accident which has occurred not only in the history of Zeppelins, but in the whole history of aeronautics Our readers may rest assured that a critical discussion of the catastrophe will appear in these pages as trustworthy information is received from G rmany.

In last week's Scientific American a brief descrip-tion of the "L. II." was published. The vessel, it will be remembered, was the most pretentions thus far constructed by the Zeppelin Company. She had a length of 487 feet and a beam of 50 feet. Indeed, she was so large that a special shed had to be constructed in order to bulld her. Unlike previous Zeppelins, she was provided with three cars instead of two. The third new car was the equivalent of the bridge of an ocean-going car was the equivalent of the struge of an occusingoing steamer; for it was used only to navigate the craft. The passageway connecting the cars was contained within the hull and was not suspended beneath it, as in the past.

No sirsing thus far constructed has ever b powerfully engined. The "L. II." was driven by four separate engines in two separate engine rooms. The total output was 800 horse-power, enough to drive the total output was not not believe the conditions, at a speed of over fifty miles an hour. A trial trip undertaken on September 6th last was considered satisfactory.

### New Railway Signal Experiments in France

ONE of the leading French railroads is engaged in making trials of apparatus for giving automatic signals to the engineer upon the locomotive in con-nection with the usual track signals, and in order to test the method on a large scale it is fifting out the lines from Paris to Dijon and other sections to the extent of 250 miles of double track, upon which there are 268 disk signals. As many as 140 locomotives are equipped with automatic devices, and these consist of contact brush mounted under the front of the locomotive, and in the middle of the track. At the proper place the track has a short place of electric rail which is curved so that it rises for a certain distance and the brush can make the contact with the surface. The current thus enters the locomotive and works a magnet device for a steam whistle placed near the usual one, but having a lower tone, and this shows the pres ence of a "stop" signal at the point in question. Corbined with the usual speed chart is a device for regi tering the present signal. The engineer then cuts off the special whistle by pulling upon a cord.

### The Current Supplement

In this week's issue of our Supplement Mr. J. J. Ide gives an account of the recent swiation meet ut Rheims, France, and the contest for the Gordon Ben--Messrs. Langmuir and Orange's paper before the American Institute of Electrical Engineers on their work on the nitrogen-filled tungsten lamp will be pub-lished in full in this and the following issue.—Mr. J. W. Fewkes' article on stone monuments is conclud in this issue.—There is a common impression that the staling of bread is due to its drying, i. e., to loss of moisture. A recent investigation by Dr. Kats, reported upon in this week's issue, has shown that this im-pression is erroneous and that the staling of bread represents a reversible change of state similar to that of red mercury iodide into the yellow variety.—The or red mercury localization the yellow variety.—The interaction between passing ships, which, it will be remembered, led to a serious accident to the "Olympic" and the "Hawke" soon after the former was launched, has been made the subject of a curoful investigation by Port. Goodson in collaboration with Mr. J. H. Thompson. Their report is published in this reach. Wook's Superaware

#### The Ten Most Needed Inventions

To the Editor of the SCHNTIFIC AMERICAN I am very much interested in the results of the con-st "What Are the Ten Greatest Inventions?" I would also like to know from you or your readers what are the ten most needed inventions or discoveries. Baltimore, Md. WILLIAM HURT.

### Wanted: A Humane Animal Trap

To the Editor of the SCIENTIFIC AMERICAN: The publication of the appeal signed by George Fos ane animal trap, wi well for a h for inowes: for a number animal trap, which appeared in the September 18th issue of your valued journal, is a step in the right direction.

I admire the humanitarian motive that prompted Mr.

I admite the humanitarian mouve teat prompted and. Howeli to write you, for to anyone capable of reading between the lines must appear in all its horrible details the death agony of millions of animals which have been caught and crucified in this barbarous manner, viz., by the old-fashioned steel trap with its terrible cruel grip.

May I suggest that if one of the humane societies would offer a prise of \$500 through the Sourstiffer American for such a humane animal trap, which would immediately kill without torture, it would be forth-A. JOCELYN H. MAGRATH. coming within a year. New York city

### A Possible Case of Telepathy

To the Editor of the SCIENTIFIC AMERICAN

I quite agree with your reply to Mr. Richardson on I quite agree with your reply to far, accession on the law of magnetic communication between human beings. The analogy between telepathic and wireless telegraphic communication seems to me most remote. A recent circumstance, which seems more than "coincidence," has upset my ideas as to any law of telepathy

Last winter, as wife of a State Representative, I spent a large part of the three months' session as a visitor in the galleries. I knew the sergeant-at-arms

in the most desultor; way. I spoke to him probably not more than half a dozen times during the session. About two weeks ago, the thought of Mr. B—came to me repeatedly one afternoon. I remembered an sot of kindness to my husband. I thought of his an act of kindness to my husband. I thought or his conduct on certain stormy occasions in the House of Representatives. Quite suddenly the thought came to me that he was in trouble. Irritated at spending ich time and imagining on a comparative strange

I resolutely turned my thoughts elsewhere.

The next day's paper contained an account of his death by drowning on the previous afternoon.

This seems more to me than accident. I am positive that I had not once before thought of him since the close of the regular session in March. Mas. X. Austin, Tex

### A Plea for an Increased Patent Office Force

To the Editor of the SCHENTIFIC AMERICAN As yours is a scientific journal, it is to be prethat you will welcome any suggestions that may offer a feasible remedy for the congested condition of the United States Patent Office. It will be observed from the weekly reports of the Official Gazette that the num ber of applications awaiting official action is ste increasing, and it is obvious therefore that the Office force is entirely inadequate to cope with the business of the Office, and some solution of the problem must be devised, or the interests of inventors and the people at large will suffer in consequence. On May 13th, 1913, the number of applications awaiting actives 27,465, and on September 30th the number his d to 30,128, this being an increase of 2,663 in four and one half months, or a yearly increase of about rour amo one natt months, or a yearty increase of about 7,000. From these figures it is obvious that Congress should provide a remedy for the existing evils, which are becoming greater every year, and that must soon be remedied or our whole patent system will be greatly impaired in its usefulness. Because of these facts will you allow us to offer a few suggestions, having in view the expediting of business in the Patent Office? First, that the number of divisions be increased from forty-three to at least fifty, and that the Office force be increased in like proportion; and second, that the number of applications pending in the various divisions be over or approximate penning in the various dynamous or equalitied as nearly as possible, so that inventors of all classes of inventions will stand an equal chance in the allowance of patents. Now it will be observed that there is a great disparity in the number of applications pending in the different divisions; in nine there are

over 1,000 in each, and in two of these there are over

1,800 in each, while in sixteen other divisions there are less than 500 in each division. Now it is obvious that these disparities in numbers should be adjusted, unless there be some substantial reasons for their retention st and that do not admit of a remedy The inveitors of our country and the world pay the entire expense of the Patent Office and leave a surplus of \$68,000 yearly to the Government, as clear gain. of these fa cts, are they not clearly titled to the very best of service and an early alle ance of all patents where the nece EDWARD W. OWENS. plied with?

Wagner, S. Dak

### How the Indians of Peru Use Coca Leaves

To the Editor of the SCIENTIFIC AMERICAN

An article in your issue of the Scientific American's September 20th attracted my notice, under the fifte What Is Cocs?

ought perhaps it might be of interest t many readers to say something more about the way, and to what extent this plant is used, principally by the Indians of Peru, partienlarly in the high altitud

In the latter part of 1910 and early part of 1911 I was at La Fundicion and Cerro de Pa o, Peru, an altitude of over 14,000 feet. I saw there the Indians chewing these coca leaves, and they surely must be a powerful restorative and stimulant. To illustrate: One day. was snowing and raining, an old Indian, ragged, dirty, and altogether a picture of misery, ambled in to the number yard, and directed his weary steps to a large pile of lime, which was partly exposed to the rain. There he sat down and drew his pouch of coca leaves around to the front, and commenced to fill his month with them. After this procedure, he stealth-ily reached down and picked up a piece of lime about the size of a hazel nut and put that in his mouth with the leaves. I was secretly observing his actions, and waiting for the expected effect. In about two minutes the old Indian's face was wreathed in smiles, and he glauced furtively from one side to the other as if he expected someone to intrude or disturb his pleasant sensations. When he thought all was secure he threw out his chest, and commenced to take notice of his tori and dirty clothing. A torn place in the knee of his emed to annoy him considerably, for he re peatedly tried to fold it up and stroke it away, as if eted it to disappear entirely, and would occasionally fleck away a particle of dust.

stonauly neck away a particle of unit.

The power of endurance of these indians is surprising to Americana. Men, women, and children are carriedy more than heasts of burden 1 saw an Indian boy not over fourteen years of age and not over clickly pounds in weight carry one hundred pounds of coal up a long hill for several hundred yards without resting.

The women are often seen with one hundred or one hundred and fifty pounds of coal in a poncho, struggling up a hill, with a baby perched upon this psucho, and the old woman spinning ilama wool, which is wrapped around her left forearm to a spool and spindle. She spins with her right hand, with apparently no thought of the load she is carrying.

I suspect that the women use cora leaves as well as the men, and also the children to some extent Atmost every Indian man is equipped with a psuch, made from a cow hide or the hide of some small animal, with the hair always on the outside

se leaves sell in this locality at five cents per pound. I am inclined to believe that cora leavemore extensively in Peru than in Chile, for I was in the Andea Mountains in Chile and never rememb ving seen them used by the natives engaged in similar work to that of the Indians of Peru

W H. REAGAN.

### Repelling Aeroplanes from the Ground

By C. Dienstbach O far as military flying is concerned, the real lesson that the contract of th military officer foresaw, the ordinary rifle proved far more efficient than artillery in forcing aviator scutts to withdraw. Field cannon cannot be discharged at high angles, and even howthers have their limitations in that respect. The experimental aerial artillery thus far constructed fails to meet other obvious requirements. The repelling of torpedo boat attricks by lattice-lips requires special ordannes which must be expable of very quick handling if it is to be of-fective at all. Yet this lesson, taught by every nary in the world, seems to have been quite lost upon those who seek to reorded our armies with artiller, for those who seek to provide our armies with artillery for the repulsion of aeroplanes. What is needed is evian serial gun so mounted on a pedestal that the pointer can haddle it like a rife, raise it at an elevation of 70 to 80 degrees, swing it around and aim it by means of a shoulder rest or butt.

It is worth mentioning that in 1871 Krupp made such a gun for the express purpose of bringing down the

balloons which easily escaped from Paris during the siege. It is obvious that the catifier of such a gun must be small, so that the piece may be swung quickly without the aid of mechanism. Large caliber is less sential because shrapnel is not very efficient if the range is not only unknown, but also subject to quick change. Moreover, iong ranges must be attained, not by large caliber, but by high initial velocity in order by large cannor, out by high minn relocity in order to carry the shell as quickly as possible to the target; otherwise it will be necessary to aim so far ahead of the rapidly and irregularly moving object that exact firing is out of the question and all alming merely guesswork. Long range is essential because adjustable eights are in a way useless against aircraft. Only a point blank fire can reach a prying aviator with any degree of certainty. It is very important to note that the point blank range increases with the angle of sight, At 90 degrees it is infinite; nt 80 to 70 degrees it is well-nigh 80 to 70 per cent of the total range.

In the light of all this it is not difficult to underwhy the high-powered modern muskets used in the Balkans, which met most of these requirements, ed as well as they did against aeroplanes could be quickly and readily pointed at the steepest angle, and the high initial velocity of their ne pointed bullets gave them a very great point blank range. These needle-pointed bullets, invented not so many years before the flying machine's advent, seemed actually to have anticipated the military aeroplane it-They increased the horizontal point blank range from 800 to some 1,500 feet. No wonder that in the recent war the Balkan pilots soon felt safe only at the great belight of 6,000 feet. The highest sight of a rifle exceeds a horizontal range of 6,000 feet by very

ilttle; yet 2,500 feet above Adrianople a Russian pilot on the Bulgarian side missed death by the lucklest chance, three bullets plereing the floor of his ear.
The German pilot Scherr, with the Turks, tells of four rifle balls that hit the planes of his machine. Three of them pierced members of the frame at a height of

The effect of musketry fire against aeroplanes in the Tripollian campaign was not so marked as in the Balkans because there were not enough skilled marksong the few Turkish regulars and the many Arabian irregulars to whom a modern rifle was not a mysterious piece of mechanism. The seasoned men of a European standing regular army, all fumiliar with muskets, would have given a better account of elves

An aeroplane over an enemy's position draws the concentrated fire of hostile marksmen, who may be scat tered over a great expanse of ground and therefore among their great numbers invariably include whole crowds of exceptionally skilled sharp-shooters

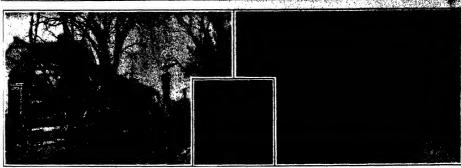

At 5,000 feet an aeroplane seems so small that it is hard to find when once lost from sight. High skill in marksmanship is essential to hit it Because rifles are always more numerous than cannon, a company of marksmen may make it uncomfortable for an aeroplane even though its height be 5,000 feet. At that distance from the muzzle the actual scattering of the bullets, even from a rigidly held rifle, is such that a certain becoming of hits is almost sure to be scored. Hence it becomes very essential to armor the men and the vitals of muchines. Since the striking energy of a buliet after it has reached a height of 5,000 feet is paratively low in spite of its tremendous penetration at shorter ranges, very light armor will serve its pur

### Panama Hat Industry in the Philippines

ONE of the ambitions of the enterprising Philippine Bureau of Agriculture is to introduce the Panama hat industry into the Philippines. The plant from which these hats are made, Carludovica palmata, is now cultivated in Java, where hats are being woven from its icaves by Javanese women and children, and the product is said to compare favorably with the common grades turned ont in South America. The method of preparing the leaves is very similar to that used in the Philippines in preparing sabutan leaves for weaving sabutan hats. The Filipinos are skillful hatmakers, and in certain parts of the islands but weaving is the chief household industry. Experiments in cultivating Carludovica palmata are now under way at the Lamao and La Carlota experiment stations in the Philippines

### A Radioactive Iron Mud

THE famous St. Antal spring in Austria deliverradioactive water of marked therapeutle value, but it has been shown recently that the mud deposited by the spring has a much higher radioactive value than the water. This is the more interesting because this mid is mainly iron oxide, Fe<sub>1</sub>O<sub>2</sub>, which on heating, dissolving, reprecipitating and drying yields increased ac-tivity. Since the emanation acts differently from those of radium, thorinm and actinium it is concluded that there must be present some new radioactive element similar to ferric tron.

### The Passaic Valley Sewer

### Plans for Securing Wide Diffusion at the Outlet in New York Bay

Fig. 1. The last twenty miles of its course, the l'assate little better than an open sewer. The sewage from a population of two thirds of a million pours into this singsids stream, and its bottom is cloudy with the second with deposits that have accumulated for years. The liquid and footling matter move leducity into Newark Bay, and eventually find their way through the Kill von Kill into upper New York Bay, whose waters are niterady surferied with sewage from New York city, thence in due course they reach the ocean. A small part of the sewage sho passes through the longer course provided by Arthur Kill and Staten Island Sond into the lower has

For years the 'Insede River has been considered a memor to health, and if was decided some time a memor to health, and if was decided some time a memor to parallel the river, from Puterson on, with a large truns sewer which would intercept not only the sewage that now pours hitch the river, but also that of several more towns included in what is known as the Passel Valley District. The area of this district is elghly square miles and it contains twenty communities or townships. The total population thus served would be about three quarters of a million. At the present rate of growth, it is estimated that in 1940 there should be 1.6 miltion himbitants in this area. The principal contributors to this sewer must always be Paterson at the head of this sewer, with 125,000 lababitants at the present time, and Newarks at the month of the Passale River, with a population now of 347,400.

As Newark Bay is cut off from direct communication with the ocean, it is planned to run the sewer under Newark Bay, and directly into upper New York Bay, and Robins Heef within the New Jersey State line. However, this has led to a great deal of opposition upon the part of New York State, which contends that the sewage must pass through New York waters.

before it can find its way to the ocean, and New Yorks sewage problem is bad enough now without having to take into consideration the sewage from a neighboring Nate. On the other hand, New Jersey has acreed to establish a treatment station on the west shore of Newark Bay, where the sewage will undergo a thorough mechanical purification. The Passade Valley Sewerage Commissioners guarantee that there will behave of angulerated particles, or objectionable deposits, and of odors due to purrefaction of organic matters outside in the sewage that pours into New York Bay; that there will be practically no greene or color and no injury to public health, or to the property of the United Nates situated in the harbor of New York; and that there will not be cough reduction in the dissolved oxygen content of the waters of New York Bay to interfere will mob te cough reduction in the dissolved oxygen content of the waters of New York Bay to interfere with major dail infe.

This guarantee is under with the indorsement of the United States, which inter-tened between the two States, and which, with the assent of New Jersey, shall have representatives designated by the Socretary of Swar to inspect the conditions and working of the sewer system at any time, to determine whether New Jersey is living up to its contract. Thus New Jersey is living up to its contract. Thus New Jersey is living up to its contract. Thus New Jersey than a mileance to New York, for the very sewage which new flows into New York, for the very sewage which new flows into New York. Buy through Kill von Kull will undergo a thorough treatment and purification before discharging into tions waters.

The method by which New Jersey expects to carry out her part of the contract is interesting. The sower, which will start with a diameter of 3 feet 0 inches in Paterson, will rapidly increase in diameter to 0 feet at Passaft, 0 feet at Suttley and 11 at Newark, reaching the pumping statlon at Newark Bay with a diameter of 128 feet. Here it will like at an elevation of 20½ feet below mean low water, and will pass through treatment works which will be described below. To carry the sweape under Newark Bay a pressure tunnel will be driven through rock 200 feet below sea level. The tunnel will be 12 feet in diameter. On the other side of the bay it will rise to 80 feet below sea level, and will continue at that level to New York Bay, tarminating at an outfall station at Bobias Resf, twe miles offshore. Here it will rise to 25 feet below sea level, so that access may readily be had to valves for controlling the flow of the sewage. From the outfall station, pipes will carry the sewage fown to a depth of 40 feet, before it will be allowed to discharge into the channel.

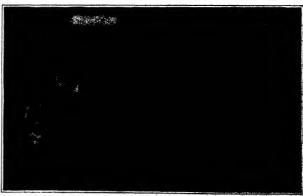

At the treatment station, the sewage will first pass through coarse ercens to remove all floating matter, and then through grit busins and fine screens. Theresfer it will be pumped through sedimentation basins or settling tanks. Provision will here be made for removing grease, foothing matter, and all solids, and the clarified effluent will be forced through the pressure tunnel to New York Bay.

The terminal station in New York Bay, as shown in The terminal station in New York Bay, as shown in our illustration, is an octapuous structure of concrete, which is the terminal station of the control of the control of the terminal station of the control in the control of the control in the future. At present only two of these outfall pipes will be needed in the future. These outfall pipes will be taked, but provision is made for third pipe which may be needed in the future. These outfall pipes are detailed feet in diameter, and they will run down the sloping banks of the reef should 50 feet part, until they reach a depth of over 40 feet below mean low tide. Here the outfall pipes will benach into discharge pipes, extreding across the current and spaced a hundred feet apart. They

ds. The New York Times offered three prizes of \$1,000, \$750, and \$500 to the men who finished first, second and third, respectively. The Aeronautical Society offered a silver cup to the three aviators who finished first, second, and third.

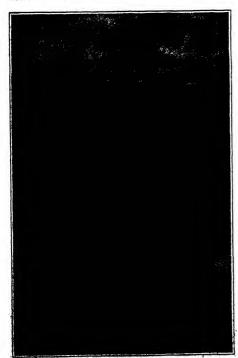

One of the entrants was Albert J. Jewel, who left Hempsteand L. I., on the morning of the derby, intend-ing to land at the starting grounds. He has not been heard from since. Two fishermen saw film drifting out to sea. It is probable that, losing his way above clouds, he perished after his gasoline gave out

### The Balloon Race for the Gordon Bennett Cup

THE international race for the Gordon Bennett Cup, which started from Paris on Sunday, October 12th, was won by the American bailoon "Goodyear," which, was won by the American balloon "Goodyear," which, with Raigh H. Upons and Raigh A. D. Preston on board, covered about five hundred miles. The American balloon "Uncle Sam," piloted by Capit H. E. Honeywell, landed after a flight of about 250 miles on the French coast nouth of Brest. Third in the race was the italian balloon piloted by Agostini. It also descended on the French coast. The "Goodyear" was the only balloon to cross the English Channel Landing within a few yards of a steep ciff on the northeast coast of England, on or a steep cuit on the normens coast or Enguild, on Bompton cliffs, near Flamborough Head, it narrowly escaped disaster. The men on board descended simply because of fog, mist, and wind.

### The Passing of the Sailing Ship

This is the theme of a report from the American consul at Hongkong, and is illustrated in the statistics of that port. Just one saling ship entered Hongkong in the year 1912, as compared with 688, one fourth of the total cutries, in 1876. No suthing ship of European type is now engaged in regular trade to Housekong, and even Chinese junks are being robbed of local business by power vessels of various kinds. In the fiscal year ended June 30th, 1912, slightly over 4 per cut of the tomasse outstook water of the Various scale. ar 1912, as compared with 688, one fourth cent of the tounage entering ports of the l'ulted Stat from foreign countries represented sailing vessels, while in 1884 such ships made up more than 42 per cent of the total entries

### The Work of Aircraft in the French Maneuvers, 1913

### Aircraft Were Not Conspicuous, But Nevertheless Extremely Useful

By Major H. Bannerman-Phillips

Till most stringent precautions were taken this year to preserve the secrecy of the orders and movements of the two adversaries. The result was to increase the realistic side of the operations, but at the expense of information. Not only, too, have spectators seen very little, but the commanders themselves, and even their staff officers, have found it most difficult to keep in touch with the course of events. Benddes taking cover

In woods, by the side of hedges, in buildings, among bushes, and under certs and wagons, and even railway trucks, during daylight, the troops in a contemporary battle (which may lest for days) will often march by lath. By day they will file, like Hed Indians, under trees and bedgerows, or lie still in the long grass a wavilling the moment to strike. Every precention has to be taken to the long the contemporary of the still of the long grass and direct the distant fire of his beavy artilliery on the closed ranks of a marching column. The result is to undervesse the difficulty of commoding every sort of unit and to make the art of way far more of an intellectual exercise than it has been even in the recent past.

Mist and rain complicate matters and the French airmen had both these and the night marching of the enemy to interfere with their observations

The basts of the grand maneuvers of all arms in France was the victualing of the armies, for which both fresh and chilled meat was to be used, the employment of the aeromentical services, and the trunsport in connection with these two services, in the sree which lies between Auch. Agen, Montauhau and Toniouse, the southern army being leased on Toniouse, the northern army on Agen. Aviation camps specially organized, so that they could be strack and packed on the forder, ready for transport, in less than an hour, were formed at each of these last two blaces.

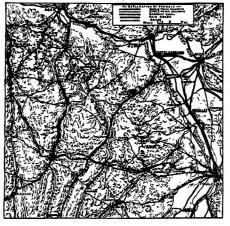

Each side had three "escadrilles" aeronianes with complete transport and cadrille" has been stand ardized as the French military aviation unit, and its personnel and material are designed with the object of keeping six aeroplanes permanently in the field. The short period of the maneuvers can only give an approximate idea of the wear and tear which the strain of an actual cam paign would bring to bear on both the huand mechanical compon unit, but fulriy conservative British estimates bused on the experiences of the work of instruction at Salishury Plain and Farnborough give a very short life to a heavier than-air machine in constant The Biltish Secretary of War has stated that if it is required to have 100 aeroplanes ready to fly at any given mont, there must be 200 to hand, and his critics maintain that in order to have 100 aeropianes efficient and ready for war it is necessary to buy 300 additional machines or the equivalent number of spare parts each year Again, the strain on pilots of aeroplanes is out of all proportion greater than on the pitots of gibles, and the present estimate of the

probable period of efficient dying on active service is three months. If the architor is not to risk physical and nervous breakdown, and the same remarks apply to serial observers. Matters will after for the better in this respect no doubt as time goes on and machines improve, but that is the reasoned opinion of experts at present

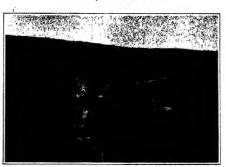

present
The transport for an "cocodrille," accordingly, is intended to carry, besides the personnel, a generous proportion of the spare parts, the field almourne, workshops,
and accophises themselves, complete, but diamounted.
All vehicles are motor-driven except the two-wheeled
prolonges: for carrying accophanes, and these have a
limber attachment, like that of a field-gun, by which
they are higherd as trailers to motor rebilese.

The complete transport consists of three motor cars and two motor cycles (for inter-communication purposcs), six heavy cars, each drawing a two-wheeled trailer or "prolonge," and two traveling workshops. These last are of similar type to those employed by the British Royal Flying Corps at maneuvers this year and known as the "Delahaye" traveling workshops.

The equipment comprises a lathe, drilling machine, grinder, shaptug machine, band saw and circular saw, each driven by its own electric motor, whose actuating

Scene of this year's French maneuvers.

Motor traction played an important part in the French maneuvers.

current is supplied from a dynamo driven, when the cur is at rest, by the 20-30 motor. Fitters' and carpenters' benches are included in the equipment as well as a full complement of metal and woodworkers' tools.

The driver is situated over the engine, thus economising the available length. For somewhat more than half the body-length the lower half of the side availage downward to the horizontal, supported at the outward corners by strong legs, thus forming a valuable extension of those space; the upper portion binges upward, forming a roof to the extension, and a currain is provided against the weather "The machine is constructed to climb very steep gradients and to traverse the worst.

It stands to reason that much money and brains have gone to the making up of these excellently organized and carefully thought-out transport units, and they have stood the test of maneuvers well, with his year and this year.

Last year the work of the acroplaces attracted into attention; reconnaiseances were carried out darty at the hours appointed on a programme regardless of the weather, and the opposing commanders were on the whole kept constantly and accurately informated to movements of the enemy's troops. No serious accident

I'm energy Froncy. No services violence, was sustained by any of he philos, shought some of the mechines suffered considerably. The services recognize restly consentrated assembled at the propose restly consentrated to the propose of the propose

Numbers of seroplanes have been bought by various provinces, societies, commercial houses, and private individuals and presented to the Government service unia and presented to the Government service that the contributions in token of their sense of the importance of French sexial supremacy. The mauhood of French sexial supremacy. The mauhood of French exists through the ranks has the cellightenment to understand the importance of the development of sertial ediclency for war purposes, and acts accordingly.

Last year the aeroplanes at the manenvers were the cruosure of all eyes. Much was expected of them, and they did much, but their work was not so systematic as it might have been. The pitots were mostly picked men, but the accoplane service was in the main more or less of the nature of a keen irregular volunteer force.

ough at this year's maneuvers aere planes have not been seen as frequently, the work performed by them has been better organized, but there has been little or no selection of individuals, either as pilots or observers, for special duties. Instead of the airmen being left to roam more or less without a definite object over dis puted country, they have been dispatched to different points with specific missions to fulfill. From the experimental point of It is on the use of the motor and not on the aeroplane that attention has been concentrated. An elaborate trial of the motor car was made in the victualing of the troops, but the most important test was that made with the new French heavy field gun, which is intended to reply to the 105-millimeter and 130-millimeter Krupp guns of the German army These guns were drawn by specially-built motor tractors of 35 horse-power, which are pro-vided with a drum and chain cable so as to enable them to pull the heavy guns out of soft ground. The tractors can carry a weight of 2,500 kilogrammes, and they can in addition draw a weight of 15 tons behind them. Their speed is 15 kliometers

per hour, and they can climb a gradient of 10 in 100 with a full load. The southern army had seven of these machines, which draw two carloads of abelis and a heavy gun on its carriage. If the seroplanes did not carch the aye their perform-

If the seroplanes did not catch the eye their performances were nevertheless signally useful and much appreciated by the generals and their staffs. One army commander declared that, thanks to his air scouts, he resily knew more about the enemy's movements than about those of his own troops.

The operations were under the personal direction of Gen. Journe, chief of the general staff, assisted by Gen. do Castolnau; this latter officer subsequently attended the British army exercises at the latter end of September.

The forces were divided into a northern and a south ern force; the former, consisting of the tweifth and eigh (Concluded on page 257.)

#### Brick Pavement in a Washout

A seject lesson in the proper grouting age of brick pavements was disclosed
by the recent Obto floods. The roadway
was haveful to a small creek which ratus
had-swelled to the proportions of a river.
A state retaining wall was wrecked and
helf the roadway washed out. The concrete base fell away in pieces, but the
helfs surface stands to-day apparently as
firm as ever and capable of bearing the
weight of an automobile. The unsupported, portion of the brick is eighty feet in
length and seven feet in width. The road
will be refilled and tamped laterally beneath the navine.

### The Pedrail Motor Truck and Trailer

It is some years store the original pedrall steam road iconsortive made it sappearance in Great Britain, and in the meantime many important developments that have been made, which have culminated in a motor vehicle and train working upon the same principle. This system aroused considerable interest at the recent Commercial Motor Exhibition in London. It is the eighth vehicle of its type, and in its design many important new features have been embodied. The most saltent of these new details is the introduction of an antifriction spring-roller chain of novel design, whereby friction is reduced to an insignificant point, the flamps and axis are frietion which existed in former models having issen eliminated entirety.

The machine has a perfect waiting action, similar to that of a certipole, in which respect in differs materially from the so-called "caterpillar." Each foot is possessed of a perfectly articulated ankie, which gives it the desired freedom of motion white negotiating road obstructions. An ingenious means of causing the feet to upproach and to recede from the ground horizontally while preserving equal spacing, has been perfected by bringing the suspension ratis into different planes when guiding the foot carriers. The horizontal approach of the feet to the ground allows of their close proximity when taking or about to take a load, and also prevents any obstructive matter such as stones and so forth from being caught and squeezed

Each pedrati places two and three feet on the ground alternately, and the forve exerted by compressed surings is so adjusted that any two feet together can carry the load for which they are designed, while one foot show would be unable to do so. Consequently, when an abnormal load is thrown upon a stuger foot it simply rises, and the obstruction is passed over without the questomary joint experienced in other vehicles. When three feet come into play, the load still is supported only, there being no lifting effect. This is because the springs are incapitally of the compressed by botts threaded through them, the boils thus being held verticitly, while their lower extremities are free to move sideways, like the qlapper in a bell, and are attached to the foot, which thes is capable of a certain side unclose content of the prings, and which is brought into play when septiating a corner.

play when negotiating a corner.

A motor-driven pedrati vehicle can be used for hauling trailers. These wagons are of similar flesism, but for steering purposes a device known as a "hinged joiat" is employed to attack the trailing wagons

Ornamenting a dam in Austria.

to the tractor. This is a cost steel framework carrying a worm attached to the front vehicle and operated by the driver. The worm engages with a worm-wheel sector on the reserved by using this vehicle in the manuer of a rudder. A motion, controlled by a pivot and guide in the hinged joint, allows either vehicle to the sideways, independently of the other. One important fenture of the mechanism is that since the two wagons are iniged vertically about a point between the centers of the two velicles, the pedralis of the rear wagon traverse the same tracks as those made by the one in front Consequently, if a train of wagons is used the last car follows in the tracks made by the tracks.

#### Safeguarding Operators in Openair Substations

HE progress of the past three or four years in the design and construction substations for very high voltage ser vice has been so rapid along the lines of securing suitable insulation and mechani cal support of conductors, that unless one seen one of the latest out-of-door types of installation for 60,000-volt operation or over, it is not easy to realize how far present standards are from work that only lately would have been thought perfectly satisfactory by transmission engineers. The accompanying photograph taken during the construction of an ont-of-doors switching station in Massachusetts illustrates this point. The importance of ade quate support for the incoming 66,000-volt es is so great that structural bridges 30 feet high and about 60 feet long been erected to support the strain insulators carrying the line conductors and the disconnecting kulfe switches which are always opened before any work can be done on a neighboring oil switch or other piece of apparatus in series with the section. As shown in the photograph the oil switches are taller than a man's head and are mounted on solid concrete foundations to cut down vibration in oper ation The insulating bushings by which the lines enter and leave each switch are of huge proportions in communison with ors are of the disk type, found so satisfactory on steel tower lines. The erection of such an outdoor switching station is a matter of a good many weeks, as every detail must be cared for perfectly to insure safe operation, and every high-ten-sion line wire must be ran so directly that by no possibility can the operator mistake it for another In this station a portion of the overhead work is designed for 110. in this station a portion 000-volt service, and the wires are spaced from 6½ to 10 feet spart Wooden plat forms will enable the disconnecting switches to be handled more effectively when the installation is completed

### Ornamenting a Dam

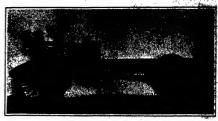

IN the SCHENTIER ABERILAN of a recent date we published an article on the growing tendency to benuilfy engineering works, as far as prossible. This has led one of our readers residing in bounark to send the accompanying photograph of a dain that is being built across the Eibe at Spindelmilihe. In Ameria, which shows that the same tendency prevails in Europe. The dain, which is to be completed in two years, is being built by Italian laborers, because the Italians are more skilled in stonework. The uniternal for the structure is obtained from a near by quarry.

A Novel Amusement Device — Clarence E Bedhent of Pleasant Ridge, Oho, has secured a patent, No. 1,083,049, for an amusement device in which a track having rollers supports a hill which is adapted to travel upon the rollers and also to navigate upon water. The hull has an air propeller and a slip is provided to guide the hull from the water on to the track and means for propelling the hull from the water on the track.

### The Motor-driven Commercial Vehicle

This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The Editor will independ any questions relating to mechanical features, operation and management of commercial motor vehicles.

A three-chain drive.

### Methods of Drive in Commercial Motor Vehicles

By Ross Babcock, M.E.

W HEN first the commercial motor vehicle came into practical existence the question as to what method should be adopted for the flust drive to the rear sate or to the rear wheels, as the case might be, was one that was readily answered and admitted of little or no argument. At that time the chain for power transmission was more satisfactory, from a motor vehicle point of view, than anything else, and as a consequence the

er transmission was nore astractory, from a motor vehicle point of view, than anything else, and as a consequence the chain and sprockets formed the last step in transmission of power from the motor to the road wheels in nearly all of the early machines, and that the judgment of the ploneer engineers was not at fault is indicated by the fact that not withistanding the progress that has been made in other forms of flust drive, the chain is in evi dence in more machines than is any other one ments of effecting the flust drive.

Whether or not the chain will maintain its supremer is a question that is difficult to answer in the face of the improvements that have been made in other means of transmitting power and the resulting multiplication of had driving systems. Chains have been made wastly better than

they were in the days of ploneer motor building; the application of scientific principles in design and construction and the employment of modern steels have had the effect of greatly reducing transmission loss and of increasing the strength and lengthening the working life of the chain and the sprockets, and the chain is the most satisfactory means available for the final drive of the heaviest motor tracks, while it is freely used in machines of all sizes and types, down to the very smallest. Improvements have been made

Combined friction and worm drive.

with at least equal rapidity in other directions, we for certain classes of machines the data in being significant by more recently developed mechanisms. Been grant, at one time extremely wasted to prove on prone to rapid wear and noisy operation, oper generation for the link beit or so-ceited "distert" chain, internal symptoms—all have been brought to stages of excellenge that permit their estimated completely machines, to say nothing of the most recent development, the worm drive, which in its original development, the worm drive, which in its original

development, the worm drive, which in its original form had nothing to recommend it except from had nothing to recommend it except going too far to say that to-day the difference access that exist in the matter of transmission efficiency between the best examples of various drive systems are so slight as to be aff but little moment as compared with other considerations, such as compactness, convenience, adaptability to general design and so on. The worm, like the bevel gear, requires close and tight housing for the purpose of excitiding dust the theory and retaining intricant. Thus they work at all times under very favorable conditions, so far as inbrication and protection are concerned. The chain, on the other hand, is a somewhat difficult thing to income, and as a result the wast majority of chail-driven machines run with chains and sprockets expeed to the dust, which

they gather freely, to the shortening of their lives and the decreasing of their efficiency. The fact that chains will operate even fairly matisfactorily under such untoward conditions expiains in no small sasure the persistence and popularity of the chain drive.

In the commonest form of chaln drive two chains drive to sprockets holted to the inner faces of the road wheels, transmitting power from a countershaft mount ed on the main frame of the vehicle forward of and parallel with the rear axis and carrying the differential gearing. The countershaft is commonly driven by bevel gears from the tall-shaft of the gearset, the housing of the differential gear and that of the gearset being either integrally formed or else bolted together to form a rigid unit. In the heaviest class of trucks this system is practically alone while in machines of from three to six tons carrying capacity it is more in evi-dence than any other method. In lighter machines employing chain drive there is more variation in the method of using chains, if for no other reason than that the difficulty of meeting requirements as to strength is much less, and consequent ly there is more latitude for conside other things. In some very light vehicles the rear axle is of the live type and the differential carries a sprocket which takes the single chain. This arrangement is often employed in small commercial vehicles with planetary change-speed gearing mounted on an extension of the crank shaft of the horizontal motor—a type of power plant and transmission that is well adapted to and very often used for light service. Light trucks with friction disk transmission of power also are fitted with single chain drive, in some cases the chair being of the silent type and inclosed.

While it has been said that the double chain drive is more commonly employed than any other one form of final drive, it should not be forgotten that bevel gear drive is the almost invariable complement of side chain drive, the bevels driving the countershaft, as already mentioned. Considering the matter from this poi view, a little of the importance is lifted from the chain and shifted to the beve gear. The beyel, however, is becoming of sing importance as a final drive purand simple. There can be no doubt that its development in the pleasure car field, in which it is practically the only aystem of final drive, has done much to further its use in commercial cars, not only through example, but because the system has been so far perfected that it can be subjected to the stre sees and the wear and tear of commercial service without fear of undue trouble either from wear or breakage. Given a pair of properly generated bevel with accurately fluished and hardened teeth, the chief requirement is an absointely rigid mounting that will permit the requisite close adjustment of the gears and will prevent movement tending to destroy the accurate alignment, our secured. Obviously the bearings must be of a sturdy type capable of withstand-ing the necessarily heavy loads without excessive wear and adapted also to sup-port the driving berel pinion at a point as close as possible to the teeth. For this purpose ball and roller bearings of sev eral forms are employed with satisfactory torque are avoided by introducing uni-versal joints at one or more points be-tween the tall-shaft of the gearset and the bavel pixton. The propeller shaft may be run through a tube forming a unit with the differential housing, in which case the shaft forms practically an extension of the bevel pinton shaft, or it may be jointed at both ends, in which case fhe is

tube may be, and usually is, omitted.

Worm drive is peculiarly interesting because it illustrates the fact that what man wants man will usually get, if he knows enough and tries hard enough. The worm drive in use before the advent of the automobile was crude, to say the least, by comparison with the present type. It was created to go and the attempt to the automobile was crude, to any the least, by comparison with the present type. It was competed and had the advantage of girling a large ratio of reduction in a

### **Electric Trucks for Every Service**

O-DAY the Electric Truck is used in 125 different lines of trade-in 41 of the 48 states. It has followed the sun around the world and the faithful, efficient Electric is doing veoman service in Canada, Cuba, England, Germany, China, South Atrica, Brazil, Siam, Australia and the Philippine Islands.

From an engineering standpoint, it is conceded that the Electric is setting the pace in

simplicity of design and construction -- economy. Electric Trucks are cutting costs where hills are unknown as well as in such hilly centres as Pittsburgh, Cincinnati, Kansas City and San Francisco-efficiency.

Send for this Book Today "The Story of the Electric Truck"

The facts and figures that you want to know about the Electric Truck are contained in this beautifully printed book of 32 years on request. Cost beautifully printed book of 22 pages - yours on request. Cast of operation - actual photographs of newest model Electric Trucks. Send for it today. Kindly address Dept. W.

## G. V. Electric Trucks

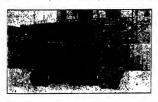

Give you 10 and more years life. Are clean, silent and odorless.

Operate 297 days out of 300 (Average statistics).

Show economy in tires, parts, replacements and general upkeep over a period of years

Promote the highest efficiency in systematic trucking, transfer work and light deliveries.

Make possible undreamed of economies in real estate investment covered by stable and wagon yards.

Design standardized since 1907. All parts of each model inter-table. Nearly 4000 in use—many ten years old.

The ex-teamster and the simple electric are a saving over the com-plex motor vehicle and the expert chauffeur-machinist.

The electric has economic law behind it and must dominate in its field.

your business acumen by getting the right machine for the right place. Six capacities: 750 lbs. to 5 tons.

Send for Catalogue No. 101, and specifications regarding our new

They are being used in practically every line of business. Their owners can tell you of the omy, dependability and durable construction of White Trucks as well as we. There is some White owner already answering the very transportation problem that is before you. Let us show you what others are doing, and what you can do, with White Trucks. THE WHITE IN COMPANY CLEVELAND Manufacturers of Gasoline Motor Care, Trucks and Taxioabs

single step-all qualities that are of th utmost importance in automobile engi-neering. By dint of the application of ethods the worm was brought to a state of efficiency that even now is no altogether credited in some cases, and it has been applied to the driving of mas of widely varying capacities-from the lightest to the heaviest, in fact. While the worm commonly is designed for a live the worm commonly is designed for a live-axle drive, as is the bevel gear drive, there are machines both in Europe and in this country in which the rear wheels are driven each by a separate worm. Shafte extend along the sides of the car to housings which inclose the worms, worm sings which inclose the worms, worm rs and the wheel bearings, which are of unusually heavy and accurately fi construction so as to maintain the relative positions of the worm and the worm As in the case of the bevel gear drive, it is of extreme importance that the worm and worm gear should be very rigid supported so as to prevent relative of greater moment in worm gearing than in any other form of power trans for the stightest inaccuracy of alignm necessarily results in an enormous in crease of friction; and lubrication, copi and unfailing, is absolutely e to the worm, which operates wholly with to the worm, which operates wholly with a stiding action and depends upon accur-ncy and smoothness of finish of its sur-faces and upon their separation by a film of lubricant for its efficiency—assuming course, proper design in the first pince

Worms are used in both overhung and nderhung forms—that is, either above or below the axie The usual reason underhanging the worm is to insure lubrin, and in overlianging the road clear ance under the axle is increased.

The least common final drive is that in which the rear wheels run on a dead axle and are driven by spur gearing, the wheelhig with the gears, being carried on th ends of a countershaft which is mounte close to the rear axle. Drive to the countershaft is effected by bevel gears, as in the case of side chain drive. It is usual to house the entire drive system, including the gears on the road wheels, for protection and for the furtherance of lubricaare employed in this type of drive, though the internal spur is the most commonly used. By placing the countershaft directly over the axle and providing the ends with universal joints turning on the same axis ring knuckles, this drive can b employed for wheels that also are steer lug wheels, and this has been succes done in a number of instances where it has been desired to drive through the front or through all four wheels

th of such points of distrib restricted in area and accessibility, cost-ly to maintain, and in many cases abse-lutely impossible of expansion and in every case only extensible at enormous every case only extensible at enor

In its infancy it is impossible to decide upon details of installation and equipent, but it can be seen that costly ment, but it can be seen that costy mis-takes could hardly be made, that original equipment could hardly be valueless, that growth could be along the lines of experiance and added equipment such as actual operation indicated, without discarding any previously scenired, and that profitable operation should follow even modbeginnings with the possibility of limit-less growth and, through experience thus gained, lead to the installation of similar systems in other centers of distribution. The field of operation is limited only by the combined tounage of the entire tr portation methods of the country, and the um total of the congested terminals

#### Are Men Better Typists Than Women?

luded from page 316.)

with their disks, or weights. Two of the buckets are made of aiuminium and weigh 1 gramme (15.4 grains) each; the others gramme (104 grams) such, the others are of copper and weigh 10, 100 and 1,000 grammes (about 1/3 ounce, 3 1/2 ounces and 35 ounces). The disks of each series are 10 in number and range from 1 to 10 units in weight, the unit representing 1/10. 1/100 or 1/1,000 the weight of the ard bucket. The subject is blindfolded and seated in a comfortable position at a table. The examiner gently suspends the standard bucket of 100 grammes weight from the second joint of the subject's index finger, where it is left hanging for 5 seconds, and is thrice "hefted" by raising and is replaced, 3 seconds later, by the other 100-gramme bucket, loaded with an additional weight of 9 grammes. The subject is asked which bucket is the heavier. experiment is repeated, with progre sively increasing overweights, until the question is always answered correctly. The limit of muscular sensibility is exed by the ratio of the added to the weight of the standard bucket.

The essential feature of the d'Arsonval core (Fig. 4), employed in measuring the auditory reaction time, is a clock with a single hand or pointer, which makes one complete revolution in each second, in front of a dial divided into hundredths. A Foucault regulator (rot-ary fan or "fly") assures constant speed for about ten minutes. An axis made in two parts, of which one is permanently connected with the clock train, and carries a feited disk which can be caused to engage with a toothed disk on the other part of the axis, transmits the movement to the pointer. Behing the toothed disk. which is made of soft from is an ele which is made of soft front, is an electro-magnet which draws the toothed disk away from the felted disk and keeps the pointer motionless while the current is passing. When the circuit is broken the toothed disk, no longer attracted by the magnet, is present against the robusting felted sink by a senine and the pointing moves over the disk.

MUNN & CO., Inc.

In measuring the auditory reaction-time with this chronoscope M. Lahy seats himself opposite the subject and holds in his hand an exciter (Fig. 5), which serves to produce a sound by striking a gong and at the same time opens the circuit of the

electromagnet.

The subject, with face averted and eyes bandaged, holds in his hand a little appa ratus, by pressing which he closes the circuit the instant he hears the sound. Th reaction-time, or the interval between the emission and the perception of the sound, is measured by the space traversed by th r on the dial, which can be read to 1/100 or 1/200 second.

In the final test the relative strength of the right and left hands is determined by the right and left hands is determined by means of the Réguler-Chéron dynamom-eter (Fig. 2). This instrument contains a spring which is compressed with the hand, but the pain produced by the rigid-ity of the spring inhibits muscular effort.

Moreover, the dynamometer take Moreover, the dynamometer takes no account of the very important factor of rapidity in muscular contraction. Hence, its indications are of doubtful value, but the results obtained by Lahy appear to prove that persons having hands of equal strength produce the best work on the typewriter.

Let us now examine the psycho-physical indications of excellence in the typewriting art, as they are given in the tables published in M. Lahy's description of his experiments. One fact is apparent at a glance. Although the results ob tained from men and women exhibit a general similarity they are not identical in detail. All good typists show the same marks of superiority, but the psycho-physiological differences between the mer and the women make it necessary to study their performances separately, and then to compare the two series of results thus ob-tained. If the men and women are listed together, in the order of excellence in various respects, the highest places will be occupied by men in some of the lists

be occupied by men in some of the lists and by women in others. Good women typists usually exhibit a marked development of tactile and muscu-lar sensibility, and an excellent memory for letters and especially for concrete phrases. The right and left hands are nearly equal in strength and their atten-tion is keen and well sustained. Their relative slowness of auditory reaction is a theoretical defect, but the value of a typist depends rather upon a combination of good points than upon a great superlority in one particular.

Men exhibit greater uniformity tha Men exhibit greater uniformity than women, but the differences between good and poor typista are nevertheless well marked. In general, men surpass women in rapidity of auditory action and, consequently, in speed of work, but are inferior to women, perhaps, in power of sustained attention.

These conclusions, however, are based upon too small a number of observations to allow them to be affirmed positively and with conviction. The results here given are merely indications which may be con firmed or invalidated by future resea

idea: "Both armies have been engaged ities: "Both armise have been engaged on the north bank of the Garonns; the Southerners have been driven back and the Northerners compelled to hait to collect and supply their forces. The Southern army having been reinforced again seeks action, and the Northern force endeavors to cut the seesary's communications running southward from Tuclouss." The systems of march adopted by the two armises is of interest; Gen. Pan sent forward the colories division as a general adward his colonial division as a general ad-vanced guard, behind whose protection his masses meneuvered in deep columns; Gen. Chomer, on the other hand, adopted the German plan of marching his whole force in parallel columns of equal strength, each orising a division, or four columns in all? The front thus covered by the South ern army—some thirty miles—was nearly double the frontage of the Northern. The first period of the maneuvers closed on evening of the 13th of September with a hard day's fighting, which, however, owing largely no doubt to the numerical equality of the two forces, left the issue undecided. The object of the Northern army was to deliver a crushing blow upon the adversary while it was still shaken by previous reverses, and before reinforce-ments could reach it from Cette and Tou-In the fighting which ensued Gen Pan was successful on his left, but his

On that date the Northern army, com d by Gen. Pau, was declared to be so far victorious that it had pressed back the enemy toward Toulouse, but Gen. Chomer's force had been able to excape actual disaster. On the evening of this day the Northern army held the left bank of the Gimone as far as Aubiet and Auch while the Southerners were in occupation of the high ground between the Gimone The 14th (Sunday) was more or less a day of rest, and there was not very much doing in the early part of the 15th, as operations were to take place that night. At 5 P. M. the Northern force began to move forward, the Gluone was crossed at several points, and the advance diately in contact with the outposts of the Southerners. These, ever, were no more than a screen tended to conceal and cover the withdrawal of Gen. Chomer's troops, who re-tired, when pressed, to a strong position on the Save. The left was the weakest portion of the Southern defense, but the whole generally was so strong that it seemed unlikely that the defenders could seemed univery that the defenders could be evicted in a single day's fighting. This proved to be the case; there was fighting throughout the 16th, and the maneuvers did not end until the following day. Gen. Chomer made the best defense possible be fore entering upon the inevitable retr and his attempt to cover this by attacking Gen. Pau's left was partially successful.

In the course of the maneuvers the

Northern commander made some interest-ing and suggestive remarks respecting his aeroplanes. He addressed himself to the pilots and observers of all ranks, than them for the excellent service they had so far rendered, and demanded great eff so as to ascertain the dispusitions of the Southern army before dark. (It turned out that these dispositions were not obable, because the enemy walted till dark before moving important forces,) While praising the brilliant performances of the gallant airmen, and the excellence of the material, which had worked throughout the maneuvers without an ac cident, the Northern commander said that a yet far more difficult task remained for new arm in maintaining the "liaison" between neighboring army corps and divisions in the same army, and in keeping the commanding general informed of the progress and condition of his own troops.

The difficulty of inter-communication between the various components of a field force of large dimensions when engaged with an enemy in other than very open country and the desirability of using aircountry and the description of using ac-craft for these purposes, as auxiliary to other methods of conveying orders and in-formation, have been emphasized by the French maneuvers and configured by later exercises in England.

NOTE When are you think her of horizon a con-

Shall we send you the name of poor motor it layers dealer

WO men stood in front of a department store in an Iowa town, and the younger one, speaking decisively to his companion, said

"Masterson, I'm going to rip out that front It's very respectable, and there is history behind it, but now that this property has descended to me, I think I can do most for my father's name by doing now what he did when he started-by striking out on up-We've fallen away behind the two to-date lines other department stores And there s good reason See how gloomy the place looks-respectable but gloomy The goods look dull There's nothing to call people in nothing to cheer them up and put them in a buying mood after they get in We've got the goods, Masterson, and you're the best sales manager we ever had But I've been around the country looking at the livest places, and I tell you that the best salesman of all is Electricity

"I'm going to put in a new display arrangement and light up that new front so as to stop people as they come up the street I'm going to make it invite them in I m going to light the whole interior so that every bit of floor space will have a real selling value Good modern lighting will not only make the goods look interesting, will not only make people want to buy, but I tell you, Masterson, it will make the salespeople feel like selling It will put ginger into the entire force

"Then I'm going to open up for better ventilition at the back I'm going to put in more electric fans-you'd be astonished to know how they freshen up the air in a place

'Another thing there are a thousand and one electrical devices—there's a good dozen for us anyway-that will transform our ways of doing business, put snap in it, make it smoother and more comfortable for the customers and ourselves be able to do a lot more work with the same people - and it's simply a matter

of plain cause and effect that we'll forge ahead. We'll keep all our good traditions—and make some

This young man who had been "around the country looking at the livest places" held a conference with his architect, then called in an electrical engi-He knew what he wanted done and wanted to learn how he was going to do it. This was a little over a year ago. Today that department store is doing 85% more business than it was doing on the day the new owner made his declaration, with only a 12% increase in its force, and has taken the lead in the volume of sales

Maybe you who read this have retail selling problems that make it worth your while seriously to consider the kind of service you can get from electricity -the kind of service you can get from your outfit and your people with electricity to help

Good light not only means more customers and more sales, but it means greater economy Good light means more sales in all parts of the store—dark, unprofitable corners are banished-it means more frequent turning over of stock-more profit,

Good air means good working conditions, more productiveness for each human unit, and it means agreeable conditions that affect the customer happily in conjunction with the cheery power of good lights

How these great advantages may be carried out in your case is a matter for the electrical man to lay be-You will be astonished at the ease and the economy with which modern outfits can be installed and operated

> Take up the matter today with your electric power and light company, or any General Electric Company dealer or agent in your vicinity You will find them more than glad to co-operate with you, and no matter how complex your problem may be they have at their command the service of any part of our organization that may be most helpful to them and to you.

#### A Standard or Safe Railroad Travel

HE recent recurrence of futal disasters on our relations has once more raised the ques-tion of the relative safety of railway travel in this country and abroad. In looking for some stand-ard by which to determine whether accidents are more frequent than they should be, it is perfectly fair to take the best results that have been obtained on some well-known system of operation. So for this nurpose, well-kinown system of operation. So for this implose, let us consider the official statistics jumblished by the littlish Board of Trude, which show that during the ten-year period ending in 1000, on all the railroads of Great Britain and Ireland only one passenger was killed for every 72,000,000 carried, which is a rate of cosmalthat must certainly be considered as highly satis-Inctory

With this as a standard, we turn to the last availwith this as a seminary and the Interstate Commerce Commission, which shows that 198 passengers were ed during the year 1910 on the steam railways the United States, during which year the total number of passengers curried was 971,683,199. This means that in that one year one passenger was killed for each 4,900,000 passengers carried Comparing these figures with the standard of safety set by Great Britain, we find that the rate of casualty in that country is less than one fourteenth as great as that in the United Stutes

In commenting upon these facts, Engineering Neur answers the objection which may be raised to the above comparison on the ground that the average length of a rallway journey is much greater here than in Great Britalo, by stating that the British statistics do not include journeys by holders of senson tickets, and that this class of travel covers a very large proportion of the short distance traffic. Assuming, says this authority, that the average of a passenger journey in Great Britain is only one third as long as that in the United States, there still remains an average casualty rate in the luited States nearly five times as great as that Great Brituin

For main years the Scientific American has drawn attention to such facts as those, and we have pointed out from these to that that the remarkable immunity from accidents in Great Britain is rendered the more remarkable by the fact that the density of traffic is much greater on the railroads of that country than it is on our own. It will be news to many of our renders to learn that on the 25,000 miles of steam reliways in Great British and Ireland more passengers are entried per manual than on the 250,000 miles of rultroad in the nited States Furthermore foggy and misty weather, which renders it difficult to observe signals, is for more

prevalent in Great Biltain than here
The admirable safety of British railway travel is due to two causes: First, the practically universal use of the absolute block signal system, secondly, the absointo obedience to that system required of the engine-men. Sintistles show that as far back as 1881, five sixths of the double-track rallway in Great Britale was equipped with block signals and that in 1804, 30.6 per cent was so conjused. The British enginemen has t operating under the block system practically all his life; and he obeys its mandate. When the semaphore ain says stop, he stops, nor does he open the throttle mutil the arm has failen. In this country we play fastand-loose with our signal systems; on many roads, on most roads, in fact, the enginement after stopping at a signal which is afgainst him, is allowed to proceed cautionsly, feeling his way to the obstruction ahead of him This tampering with the block signal system (we call it nothing less) is shown, furthermore, in the continuance of the inefficient and dangerous practice of leack-flagging.

Railway travei in this country can be made as safe as it is anywhere in the world by installing the block system on every road, and by revising our rules of oper-ation so that the signal indications shall be absolutely obeyed. Furthermore, in view of the fact that discipline has not yet reached the high standard which, alone, can render the best mechanical appliances fully efficient, the automatic stop should be in effective preventive of disregard of signals.

#### Magnitude of the New Subway System

OT many people realize the magnitude of the work which is being done in extending the sub-way system of New York. So quietly and unthously is the new method of excuration being carried on, that the residents of New York are not confronted by any physical evidences of the really great magnitude of the medertaking, such as marked the construction of the first subway. Yet it is a fact that the building of what is known as the Duni System involves an expenditure of capital that is over one half as as that which has been invested in the Panama i. The canal, when completed, will have cost about \$375,000,000; it will cost \$200,000,000 to construct the new city-owned aubways.

The latest reports of the engineers of the Public Service Commission show that there is now under contract \$83,000,000 worth of work on the new subway, and that the average daily force employed is 7,000 men. About two fiths, therefore, of this great work is alread; under way. Before the end of the year con-tracts to the value of about \$60,000,000 will have been let, which means that nine months after the signing of the Dual System operating contract, actual construction work will be in progress on three quarters of the

The total length of the new system will be about ighty calles, of which forty-five miles will form an extension of the present interborough system and thirexcusion to the present interpropagate system and thir-ty-five milies will represent the New York Municipal system. These figures, however, cover merely the length of the road; and since the subway will consist of two three- and four-track lines, the shugh-track mileage will be not far short of 200 miles

#### Radio-telegraphy and Safety at Sea

IIE fact that the burning steamer "Volturno" was able to summon to its aid by radio in sages no less than eleven steamers, gave addisuges no tess than eleven steamers, gave additional proof of the priceless value of this means of communication in the saving of life at sea. Not that any such further proof was necessary; for Marcon's great invention had already established its position as one of the most merciful aids to fire saving of immun life. in all the history of invention

It was inevitable that radio-telegraphy should hold s prominent part in the discussions of the Internstional Conference on Safety at Sea, which is to be held in London, on Navember 12th of this year, and we note that Secretary of Commerce Redfletd's committee on this subject has sent in a reco ce, which appears to cover the subject comprehen-

The committee proposes that efficient apparatus radio communication be required on all ships in foreign trade which carry fifty persons or more (passen-gers or crew, or both combined), navigating the ocean between ports more than 200 nautical mil one another; and that apparatus, to be deemed efficient, must transmit messages with sufficient power to be received by day over sea, at a distance of at least 100 nantical miles, by a ship equipped with apparatus equal to that of the transmitting ship. It is further second ended that an auxiliary power supply should be provided, independent of the vessel's main electric power plant, which will canble the sending set for st ast four hours to send messages over a distance of at least 100 mantical miles by day.

There is an echo of the "Timple" disaster to the recommendation that two first-grade operators should be required on all such ships maintaining a constant service, also on all such ships carrying 100 or more passengers; that one first-grade and another first or second-grade operator should be required on all other such passenger ships, and that one operator (first or second grade) and one cargo operator or watcher ab be required on all such cargo boats.

#### Chimerical Weather Forecasting

HERE has recently been a marked recrudencease of the unorthodox weather prophet. Though that the unorthodox weather prophet. Though the unorthodox of the land, his activities fluctuate under the influence of several factors, one of which is the amount of advertising he receives through the efforts of scientific people to discourage bim.

one present case he seems to here. In house cleaning is the Westler. In too, for an indication that the mails service has been product the mails service has been profe that the time has come for the question for have his iunings; or it may be that his presen is merely the usual reaction of an atmorphis miss; is any strong impression of the involves, the impression in this instance being that produced by the instance ate notoriety given a few months ago to Weather for reau affairs. However this may be, an unpresidents number of more or less fautastic schemes for predicting the weather of to-morrow, next week, and next year the weather of to-morrow, next week, and next; year have lately come to light, so that it seems threely so say a word on the general subject of unselessible weather furcesting—with the premise that we are dealing not so much with "falses" as with delaisons, though the former have figured largely in the history of this subject.

A weather prophet's confidence in himself is always in inverse proportion to his knowledge of the laws atmosphere. The intelligent meteorologist is the st modest of forecasters, for he realisses more keesing in supone clear the other conditions with which he has to deal, and the extent to conclusions are likely to be vitiat known factors in the problem. His facilities have been much improved in recent years by the broadening of the weather map, on which alone rational predictions can be based. At Washington a map is drawn every ruing showing the meteorological conditions, reported anorming snowing the meteorological conditions, reported by telegraph, at a chain of stations extending around the globe. With the skil of this map predictions are now made, in very general terms, for a week in ad-vance. Nevertheless, scientific weather forecasting in still an unsatisfactory process, so far as it relates to the ordinary fluctuations of heat and cold, rain and sunshine, though it fully justifies its existence when it comes to deal with such definite and momen currences as storms and cold waves.

The undentable imperfections of legitimate forecast-ing encourage the activities of the charlatan and the ing encourage the activities of the charletan and the crunt. Thought the latter may be an hooset incoranus, there is usually enough method in his mediones to entitle him to find a incretit market for his prognosti-carious. He is supported by the same public which eartheast the publishers of grossly unacholarity lexico-graphical works, obsolute attasses, and the like, and his hippilest hunting ground is the United States of America. It is said that certain promosticators earn incomes of from five to ten thousand dollars a year by the sale of their predictions to newspapers and almanace. Most of these predictions are of the 'longrange" variety; i. e., they are made up for a year or more in advan

In the typical case, the prophet (when he is not a deliberate fraud) is a man who has not sufficient in-tellectual stamina to pursue the long and rugged road tellectual stamina in jursue the long and ranged road of scientific investigation, but who functions that by a peculiar dispensation of Providence he has hit upon a short-cut to the truth. Moreover, the particular mare's nest discovered by one of these persons has tunually been discovered by a great many others; so that the "systems" of the pseudos-destrift forecasters fall into a few well-defined clauses. By far the most numerous aroun of promoticators ascribe supreme influence in meteurological matters to the moon. Another group stakes its reputation on unmpots. Some years ago the hypothetical planet "Vulcan" was a favoribe with these seers. Others exploit that perennial refuse of ignor

seen. Others exploit that percentain refuge of ignor-ance—electricity. And so co.

The reputation of the forecasters—perhaps even of the scientific once—with the mass of humanity is saved by the fact that, with our changeable, waster, even the wildest predictions must frequently hit the mark. Moreover, if a change in the weather predicted for to-day falls to materialize it is likely, in the ordinary course of hasture, to come to-morrow, and the sulght delay in the verification of the forecast is apt to be viewed indulemently by the pusher by

dealy at the vertices of the forecast is app to or viewed indulgently by the public. Weather forecasting has a private commercial enter-prise is, on the whole, more incritive and dignified than, fortune-telling, and does not, as yet, come within the purview of police and post office inquisition

Propolis for Sargical Desatings.—The resignant exhibitance collected by beas from the buds of trees and used by them to stop up crevious in the lives, has just received a newl application in surgery, according to \$1 Headwiden. When this viscous substance is distilled in the wards state there is obtained a brownish liquid of uncolous state there is obtained a brownish liquid of uncolous characteristic income as propolition. When this is opposed with a contract of the state of the st STORY BASE VERY TO THE STORY

Manufacturering.

White Miteriers Lais. The formulas of Mirafores in signs October Ist, when a buildined was placed use the drainings of twe' in the spillway dam. It is exceed that the fall with the full to the test of the spilly dam on November 8th, and to the normal operative of 85 feet shows the east by December 8th. Should be deathed to fill the laise carlier, the water may be swyn from the high level of the Gestun Lake and letters out through the outvot of Pedro Miguel looks.

Checostic as a Panearvative of Telegraph Peles.—It is estimated by the Canadian authorities that every year some 600,000 telegraph and esleptone poles have to hergidated because of their decay. Universide red coder poles has fire \$0 junet; if the eronocies is put on by the himsh-they last 18 years; if they are task-dispect hergins 20 years. Walte coder has a fire respectively of 14, 17 and 22 years, according to the treatment, and yellow place 10 years. It is estimated that recibiodes treatment would save upward of 200,000 poles

Recreased Use of Locametive Superheaters.—There was recently held at Cassel-Wilhelmshöbe a celebration to commensurate the equipment of the 25,000th locametive with the Schmidt system of superheating, which has now become a standard and increasingly popular has now pecome a standard and increasingly popular feature of Locemotive practice. Dr. Schmidt's first superbaster to be applied to locomotives was installed in 1898 on some origines of the Prussian State Railways. Schmidt's pioneer work and its nucesses encouraged com-petition. By 1910 some 5,000 engines had been outpiped; 10,000 by 1911, and 30,000 in January, 1913. To-dily the figure stands at 25,000.

The English Channel Tunn The Baglish Channel Tunnel.—The recent conference on Franco-British traffic has further stimulated the awakanad interest in the proposed tunnel beneath the Strate of Dover. It is proposed to build for parallel tinnels, which will vary from a straight line in order to remain all the way in the impervious gray chalk. The landing points will be to the west of Colais and to the west of Dover. On the Presch side, connection will be made with the Chemin de fer du Nord, and with the Stuff Eastern Line in England. Drainage hosdings will be run from the lowest point in the center of the tunnels to the shore on either side. Parlament is shortly to be asked to sanction the undertaking.

Traffic Over the Forth Bridge.—In the first year of operation of the Forth Bridge, from March, 1990, to March, 1991, there erossed over the Forth Bridge 37,610 trains of a total weight of 9,941,612 tons. In the year March, 1913, there crossed the bridge, 62,944 of a total weight of y,941,012 form. In the year charce, 1912, to March, 1913, there crossed the bridge, 20,944 trains, an increase of 40 per cent, while the total weight increased to 15,584,410 tons or about 60 per cent. This bridge still remains the largest of its kind in the world. It has two spans of 1,710 feet each, the next longest span It has two spans or 1,10 feet each, the next longwar gas-being that of the Brooklyn Bridge, which is 1,595 feet, while the Williamsburg Bridge measures 1,600 feet between towers. Those two last named are suspension bridges and the Forth Bridge is a cantilever structure.

The Largest Wood-stave Pipe.—The Northwestern Electric Company of Portland, Oregon, has recently built for the conveyance of water what is, so far as we know, the largest wood-stave pipe yet constructed. It is 13½ feet in diameter, one mile in length, and it serves as the flow line from the dam to forebay. Acserves as the flow line from the dam to forebay. According to details given in the Següerene, Neue, there are ninety-four 4-inch staves around the circumference, the commal length of which is 18 feet. The construction of the pipe salled for over 1,500,000 feet is the ropport, 475,000 feet in the credit soid 210,000 in the mud sills. The staves were laid without tongue or grover, there being a steed down plant in one and of each stave to make tight the butt joints. The pipe was laid upon a bed of solid ground and, to stiffen it against distortion, it was earnied in supporting credies which were speace four and 'then half feet apart on tangents, the saddless being carefully cut to shape.

the anddies being carefully out to shape.

Resignised to the Second Claim.—The recent statement in the delty press to the sifect that the North German Lloyd Steamable Company is about to patter the "Kaiser Whilehim des Grosses" Front its express service, and that it will rename the vessed and robuild it for ecound and their date and storage treits, removing the first cabin accommodations sitegasher, serves, to resind us how the transatilatuit figure of one decode become the second class ships of a later day not far removed. Transatiantic services will result the time when this favored ship make her first opposyncies, and by overeing the passing at an Average rate of 22½ inchies an hour, received the so-called "blau ribbon of the Alabette" losses the "Leanable" of the Cusard Line, which land raised—the vessed to 22.51 knobs syctosy for the "links, legs. A slighter reconstruction and resinglifement of the cusardiant, "so there recons" before, these tensors are supported to or three years are, when the 225-facing "Resinguistics".

#### Electricity

Etiession of the Pensnytymia Railroad Electrical Zess.—15 has been announced that the Pennsylvania Railroad will extend it electrified zone to Blizabeth, N. J. This is a step toward the electrification of the entire New York division, which will probably be ac-complished within the next few years.

Wired Dwellings for Rent.—An enterprising electric light company in Muncle, Indiana, is advertising houses for rent which are wired for electrical con-veniences, the idea being to keep wired property oc-cupied, which of course is to the interest of the company that supplies electric light and power. Another objet is to induce owners of property to wire their houses.

The Emergency Force or B wire tear nouse.

The Emergency Force or B allidaya.—The electric light company of Marion, Indiana, has experienced considerable difficulty in securing a force of repairment or re-establish service interrupted on Rundaya and holidays. The difficulty has now been overcome by requiring the repairment to telephone to the central station their whereabouts as soon as a storm break out. In ease of any interruption, the manager may then collect a sufficient crow of repairmen in a very few minutes.

Electric Locomotive for the Canadian Northern Electric Locemotive for the Canadian Northers Railway.—Orders have just been placed for seven loo-motives and eight multiple unit motor car equipments for the Canadian Northern Railway terminal in Montreal. The locomotives and motor ears will use direct current at 2,400 volts. They will be equipped with two commutating pole machines in series with 1,200 volts across each motor. Electrical energy for operating the locomotives and motor cars will be received in the form of 3-phase, 60-cycle, 11,000-volt current, which will be transformed by motor reservator sets to 2,400 volts. transformed by motor generator sets to 2,400 volts direct current. Each locomotive will weigh 80 tons.

Ossaissed Chicks.—A poultry man of Waltham, Mass, says the Electrical World, is using electric consisters to reduce mortality in the hatching and broading of chicks. Ordinarily 24 to 40 hours clapsed from the time the first chick peeps forth from its shell until the last one appears. But the use of cone interests at the chickes, included they are contracted to the cone of the unus une sat one appears. But the use of ozone in-vigorates the chicks as indicated by a recent hatching which came out in ton hours. Furthermore, the chickens are uncommonly strong and robust. Experiments are now being extended to purify the hen-poisoned ground ders in an attempt to save a portion of the t mortality which occurs after the young cens are batched.

Searchlight on an Observation Tower, .-The "Fast ail" leaving St. Paul and Minneapolis every evening for Chicago carries a search lamp on the observation platform of the last car. This illuminates the landscape along the line which parallels the Mississippi River for over a hundred miles, and gives the passengers a very pleasing outlook. The search lamp is used on the 60-volt train lighting circuit and takes 20 amperes. The electrodes are placed horizontally, and after being focused they are kept in adjustment automatically. The lantern which is 13 inches in diameter stands on a pedestal about four feet high, and takes up 16 square inches of the floor space of the observation platform.

Passing of the Belt.—In a paper road before the American Institute of Electrical Engineers at Phila-delphia, Charles Fair discussed the passing of the belt, and showed how that most dangerous piece of mechand showed now that most cangerous piece of meca-nism in the factory is being displaced by the individual motor mounted on the machine. In considering the improvement brought about by the electric motor in the factory one should credit it not only with a great saving in power, but also with a great reduction of injuries asving in power, not also with a great reduction of injure to employees. Although America was the pione in motor-driven machinery, it seems that Germany showing more progress in this line. Nearly all machin in Germany are now direct motor driven.

The P. A. Y. E. Car la England.—At a recount conference of the Municipal Transvays Association at Shuffield, England, a paper was read on "hay-as-you-cuter" cars. Referring to this paper editorially, the Biscircian (London) asya: "The policy of the American transway authorities is to look upon every passenger as a thief, and every conduster as a thief until the contrary is proved. Thus it comes shout that many ingenious methods have been devised in the United States for rendering absolute the certainty that every passenger shall pay his face, and every conductor shall turn in all the money be collecta." However, after thus supercilinesty referring to American practice, it adjults a that the experience with ears of this type at Leignstein he. been againstancy, which would indicate that the American policy is not so bed after all, also that British conductors and Leveling public are not all overseroguidness in first dealings with the public service expension. There are some objections, however, to The P. A. Y. E. Car in England .- At a recent conover-scriptions in their cleanings with the panne service scriptions. however, to the use of P. A. T. E. case in Great Britain, owing to the complication of their film system. In Glasgow, for instance, there is not route where the farce range from 1/41 to 71/41, and there are 47 overlapping 1/41.

#### Aeronautics

This Airship Can Pick Up Its Stores. - In patent No. 1,070,197, to Charles Scott Snell, of London, England, an airship is provided with a grapple device suitably connected to a winding apparatus carried by the air-ship and a suitable carrier for a load, all so arranged that the load can be picked up by the airship during its flight without severe shock

Launching a Parachute by Power - Dinnel W Adams, of Glendale Springs, N C, has secured patent No. 1,069,662, in which a parachute has a tubular stem which forms an outer shell and is adapted to serve as a motor cylinder A source of motive power is connected with the interior of the tubular stem and controlled in order to launch the parachute safely.

American Aerodynamic Experts to Study Abroad.

Assistant Naval Constructor Jerome C Hunsaker,
U. S. A., and Prof. Zahm of the Smithsoman Institution, formerly connected with the Catholic University at Washington, will soon go abroad with a view to inve gating recent foreign developments in aviation Hunsaker has been detailed for duty at Boston pre-paratory to his assuming charge of an aviation course

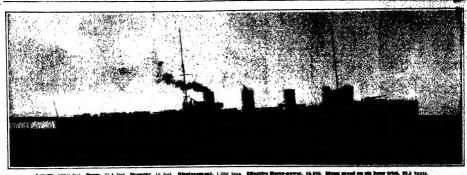

A Parachute Attachment for Aeropianes. Joseph \ Steinmetz of Philadelphia, Pa., has patented, No. 1,007,-559, an aeroplane which has a transverse frame to which the planes are fixed and a frame transverse to the first frame with a parachute stowed at substantially the intersection of the two frame members and connected rs and connected by tension devices with the ends of the frame members. The parachute is liberated by means under the control of the operator

An Aeroplane Stabilizer. - Henry C. Fisk of Stafford. An Aeropiane Stabilizer.—Henry C. Fisk of Stafford, Com., has secured patent No 1,072,710 for stabilizer for scroplanck, in which a stabilizing plane is arranged above the supporting plane and has a central portion surrounded by an upwardly and outwardly extending rim, making the stabilizing plane in the form of a dish with a flat central portion. The patentee claims that experiments have shown that the stabilizer will return acroplane to an even keel no matter what position acroplane is when it is launched in the air, provided the aeroplane is when it is launched in the air, province, the height at which it is launched is sufficient to give the stabilizing plane time to perform its function

Aeroplane Radio Equipment. -The United States Government has been quietly but steadily carrying on a sories of experiments with wireless apparatus on sero-planes. The Signal Curps wireless messages have been sentfrom a height of 1,500 feet and received at a station almost 15 miles away, while other messages have be taken easily from machines 2,500 feet in the air The radio equipment used weighs complete about 75 pounds and has a radius of 30 miles. The electric generator and has a radius of 30 miles. The electric generator is friction driven from the flywheel of the engine and has an output of one eighth of a kilowatt. The antenna is of the hanging type, the wire being would on a reel when

Aeronautical Meteorology in France. -The first meet ing of the commission organized under the auspices of the Meteorological Society of France to study the relations between aeronautics and meteorology was held in Paris May 30th, under the presidency of Col Rénard, and was attended by representatives of the Ministry of War, the Central Meteorological Bureau, and the principal aeronautical clubs of France. The commission voted to publish an account of the sources of meteorological information available for aeronauts, d passed a resolution in favor of the establishment in France of a network of pilot-balloon stations similar to those constituting the aeronautical weather service of Germany

Exploration of New Guinea by Airship. The plans of Lieut P. Gractz for exploring the interior of New Gulnea by means of an airship, brief mention of which has already been made in these columns, have now made material progress, a commutee having been formed in England and Holland to linance the undertaking, which is expected to cost about \$750,000. Designs for the airship have been drawn in Berlin. It will be 320 feet arsing nave occur arriven in Ferrin 1 with constructions by 60 feet in diameter, will be able to rise, under normal conditions, to an altitude of about 12,500 feet, and will make a maximum speed of 34 miles an hour 11 will be equipped with two 100 hose-power motors. The base of the expedition will probably be Main, where a base has been established by the Sepik expedition, now in the field. A portable shed for the airship and a gas-generating plant will be set up at this point. A series of trips will be made from the base, in each case to ome previously selected point on the coast, which can some previously setested point on the coast, when can be reached in one day. Another has station will probably be established for the exploration of Dutch New Guines. As pointed out in Petermanic Mit-teriangen, this project not only gives promise of securing, with the aid of such instruments as the zero camera and and off the photoperspectrograph, more rapid surveys of the interior than are possible by ordinary surveys of the interior time are possible by ordinary methods, but also of furthering ordinary terrostral explorations by saiding in the establishment and provisioning of stations in places now difficult of access.

#### Russian 37-knot destroyer "Novik." the fastest sea-going ve

#### Fastest Vessel in the World

By Our Berlin Correspondent

T HE world's fastest seagoing vessel has recently performed its trial runs cording to German press notices, the Russian torpedo-destroyer "Novik," built in the shityards of Messre Vulcan-Werke, in connection with the official irial on the measured mile, with her trial load, has resolved a puen made of 27 knot, the has reached a mean speed of 37 knots, the maximum speed being 373 knots per hour. Some days afterward, the vessel rwent the continuous six hours' trial ided by contract The speed preprovided by contract scribed for the Irial, viz., 36 knots, was not only reached, but exceeded considerably, a mean speed of 362 knots, throughout the six hours, and a mean speed of 86.8 knots during the last three hours being obtained The englues and bollers, in spite of these high speeds, never were pushed to the limits of their capacity, and no smoke issued from the funnels of the bollers, which were fired exclusively with liquid fuel.

The "Novik" is a turbine-propelled yes sel. The following gives some of her main

Caia:	
Length between perpendiculars	326.9 ft.
Maximum breadth	.31.4 ft
Displacement	1,250 tons
Draught	10 ft
Engine output 36,500 eff 1	torse-power
Contract speed	36 knots

rew . . . . . . . . . . . . . . . . 140 men The "Novik" mounts four 4-inch rapidfire guns and four torpedo-tube sets. She is the only vessel of her class; but Russia is building eight destroyers of 1,050 tons and 24 knots speed

#### The Most Rational Source of Power Tapping the Sun's Radiant Energy Directly

S CIENTISTS have known for many years that mechanical power to any desired amount can be obtained from the rays of the sun, and have measured this power very accurately, but owing to its diffuse nature, its collection for practical

purposes presented very many difficulties. Some seven years ago, Mr Frank Shuman of Philadelphia attacked this prob-lem seriously with a well organized force, and the backing of men of means, and has now in operation at Cairo, Egypt, a very practical and profitable irrigation plant deriving its power entirely from steam generated from water by the rays of the sense that the plant has now been running steadily since June, pumping water at a rate sufficient to irrigate over a thousand acres of land.

The first trials were made on a very The first trius were made on a very small scale. Material after material, idea after idea was tried. By a process of elimination and addition and a gradual increase in the size of the trial plants, a practical method of using sun power was into the problem was thoroughly investi

in power plant as it was set up in Egypt for a test

Sun heat absorber which catch s the sun's rays upon mirrors and concentrates them upon the long boiler in the center.

View showing the irrigation of land by sun power.

Looking into one of the al

gated, and one difficulty after the other being overcome, finally the plant now in successful operation in Egypt resulted.

Sun power plants once course, dispense with all constructed, of se with all fuel, while in order to be practical and commercially profitable, they must conform to the following requires

1. They must not cost so much to construct that the interest on the cost over and above that of a coal burning plant of equal capacity will appul the profit made

y the saving of cost of the fuel.

2. They must be constructed of such material and in such a manner that few repairs are needed, and so that they will st very many years.

S. They must be constructed strong enough to stand the heaviest gales that may occur in the localities where they are erected.

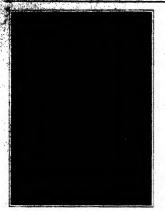

4. They must be sufficiently simple for anyone capable of running an ordinary coal burning plant to be able to run them.

The present Egyptian plant fuffills every one of these requirements. Its cost is kept down to reasonable limits by construction to the cost of the cos structing the entire frame-work of the heat absorbing portion of the plant out of simple structural pieces, all of similar simple structural pieces, set or similar design, and formed quickly and cheaply by ordinary machinery. The mirrors are made of ordinary window glass, silvered and protected in a special way, and cost only 5 cents per square foot. The foundation posts are of concrete and made in place. As far as the engine, pump and auxiliaries are concerned, these are the same as in any good coal hurning steam plant, except that the cylinder of the engine is larger, owing to the fact that low-pressure steam is used. The heat absorb-ers and steam generators are constructed entirely of concrete, steel and glass—all materials which will last for very many veers in the tropics. The iron being easily accessible can be painted every six or eight years. The heat absorbers are all engate years. The heat necorpors are all constructed to stand safely a wind pres-sure of 30 pounds per square foot—more than that caused by any gales occurring in these sortions of the tropics.

The sun power irrigation plant consists of the heat absorbers, five in number; a low-pressure reciprocating condensing steam engine of 100 horse-power, a reciprocating pump, and all the necessary auxil-

As the entire engine and nump portion of the plant is practically identical with those of ordinary coal burning plants, except that the engine is specially invented and constructed so as to run very ecoand constructed so as to run very economically on low-pressure steam (for a description see Schenving American Sur-Flement, July 19th, 1918, p. 29), we will remaint. July 1263, 1918, p. 20), confine ourselves to a description sun heat absorbers and steam gen-which will take the place of the furnace and stack of the coal of

Ordinary electric lights are not suitable for the application of ultra-violet rays. Specially constructed lamps are designed and eperated for that nurness.

View of an ultra-violet ray apparatus intended for use in sterilising water in a physician's office, an operating room of a hospital, or other places for treatment of patients.

When the human skin is exposed to sunlight the utra-violet rays penetrate and cause a dissociation of some of the chemical substances in the blood and tissues.

## How Inventors Use Ultra-violet Rays

#### Making the Invisible Radiations Do Man's Work

For one were to take a trip 8,000 miles long in perfoct darktees all the way except for a distance of one linch, for which short distance the way was brilliantly lighted, would it be supposed that one would gather a very good dose of the country and scenary traversed? In the innegitary trip one would be under the same and the same traversed of the country of the same traversed of the country of the same traversed of the country of the same traversed of the country and country traversed to the same traverse practically all observations of physical phenomena have been made by visible light the proposed of the other, the medium in which light he proposed of the other, the medium in which light he proposed of the other, the medium in which light he proposed of the other of the country of the same traverse of the country of the same traverse of the same traverse

In the appended table is seen a diagram of wavelengths and the phenomena with which they are most commonly associated.

Cheen active

Ch

Now as indicated on the diagram, the upper rays of longer wave length are beat waves, and the lower ones of shorter wave length are chemically active rays. These shorter rays below violet are known as pitraviolet or chamned rays, and it is with those that we are st prejent inherented.

These shorter may below violet are known as pittriviolet, or chemical rays, and it is with thouse that we are at present interested. The tight from the sun contains all the rays in varicius proportions from the inference instead. (1) on our table. Including the ultra-violet rays marked (1) on our table. The tight higher of the sun on it actions the cards con-

AN MARKAGE LINES AT

tains all these rays. It is altogether possible and most likely that the sun gives all these various redistions and possibly others, but it is not possible to determine this as a fact for the waves may be of such slight intensity that they do not reach us in sufficient quantity to be admessible. Ultra-violet rays are very quickly absorbed by the atmospheric gases, and it is only a comparatively small part of the ultra-violet light that is given off by the sun that ever reaches the earths arriace, but the rays that do reach the earth play a very important part in the welfare of the biological inhabitants of the earth.

One fact determined when the properties of uitra-

Ultra-violet ray electrode designed by Dr. Charles

ipores of Nosema bemberis (silk worm). Photo

violet rays were first investigated was that the ultraviolet rays have a stimulating effect on plant and animal life, and as early as 1500 an experimental hothous, using windows of bits and the same than the same than the same to determine the best conditions of the and evolute gissers to determine the best conditions of were to be the same and animals. Although the offers were to this reducery land and filling same are almost controlly onesses of ultra-violet rays. In effect the arrangement merely shut off a servicial per cent of both best rays and ultra-violet rays.

In more recent years the United States Department of Agriculture has carried on very extensive and ex-baustive experiments along the same lines. The results obtained from these experiments brought out the fact that the ultra-violet rays are a stimulus to plants, espe-cially at certain stages of their growth. However, the light does not have the same effect upon all vegetation and in some cases certain plants were greatly aided by the light, and in the same light the growth of others was retarded. The light for these experiments was obtained from mercury vapor and lamps, for the incandescent vapor of mercury is peculiarly rich in ultra-violet rays. In regard to the effect upon plant life in general, the first thing to notice is that ultra-violet rays have a strong chemical effect and are the part of the light of the sun which is very necessary for the life of the plant to enable it to breathe The green the rise of the plant to engoin it to breather. The green chlorophyll in the leaves and growing stress is the chemical substance, which, under the influence of these chemical, actinic or ultra-violet rays, dissociates the carbon dioxide in the atmosphere into its elements carbon and oxygen. The plant absorbs the carbon and the leaves exhale the oxygen Phints in the absence of chemical rays of light soon turn pule, because of their inability to absorb and convert the atmospheric curbon dioxide which is a vital part of their nutriment. At present it is not practical to aid ultra-violet rays arti-Scially since they are costly and difficult to apply. Ultraviolet rays if generated by electric light must be very powerful to be of any effect, as these rays are quickly absorbed by the air, and very little of this form of asserbed by the air, and very fittle of this form of light reaches the plant unless it is near the source, Ordinary mercury are lamps are not suitable as it is difficult for the raps of short wave length to pass through the glass bulb. Specially constructed mercury are lamps with quartz sides are very good for propagaon of waves of short length. But at present such installations to stimulate plant growth are too costly to be of broad commercial value

The effect upon animal life is somewhat different.

The effect upon animal life is somewhat different. Ultra-riolet rays are very deadly to micro-organisms and bacteria. Upon animals of higher order the light seems to have a very beneficial effect as the more highly developed automatically adapt themselves to the light and soon protect themselves from the effects of ultraviolet rays. This is the well known sunburn and tan which is Nature's protection against chemically active light. When the human skin is exposed to ambight the ultra-violet rays penetrate and cause a disacta-tion of some of the chemical substances in the blood and tissues, this causes pain and inflammation. The effect is that a layer of pigment is soon deposited in the skin which acts as a screen to these chemical rays, enting further damage.

Ultra-violet rays are very deadly to all bacterial life and are of especial use in killing off the micro-organ-isms which cause disease. So beside the stimulating effect which sunlight has upon the human body it has a great bactericidal value. Hence, the doctrine of fresh air and sunshine is eminently correct. And sunshine ough a window is not nearly so beneficial as direct sunlight, as these ultra-violet rays have great difficulty in passing through glass. This is very well illustrated by photographs taken by Prof. R. W. Woods of Johns by photographs taken by Prof. M. W. Woods or Joins Hopkins University. In one case a photograph is taken of a doorway with part of the light passing through the glass door and the rest of the light through the unobstructed doorway. In ordinary sunlight the glass door appears perfectly transparent, but when the same view was taken by ultra-violet rays alone, the glass in

door appears porfectly transparent, but when the same view was taken by ultra-violet rays alone, the glass in the door totally obstructed the rays. Medical applications of this principle have been made in the use of ultra-violet rays and X-rays for the treat-ment of certain diseases. The general effect of ultra-violet rays, radium emanations and X-rays is quite similar except that these last rays are far are appear-

violet rays, radium eminations and x-rays is quite similar except that these last rays are far more power-ful in their chemical and penetrative effect, and are in general far too powerful for continuous application. In 1909 Finaen, a l'annish physician, opened his fam-ous tight inettute in Demnark for the treatment of skin diseases by the application of germicidal ultraakin diseases by the application of germicidal utira-violet rays. He used as a source of utira-violet rays, an arc samp of high power. This lamp was inclosed in a cylindrical casing which served somewhat as a reflec-tor. At the bottom end of the cylinder were arranged four tubes which served to direct the rays upon the patient to be treated. Quarit lenses were used to gather and transmit the ultra-violet rays. These tubes were filled with clear water to coot the tubes and to cut out heat rays. Water is quite transparent to ultra-violet rays, but showths het vans receitly. The national volet rays, but absorbs heat rays readily. The patient is placed so that one or more of these tubes can be directed upon the diseased parts and the lower end of ng the quartz crystal is then pre upon the skin of the patient.

upon the skin of the patient.

The ultra-violet rays have not very great penetrative power, and hence, are suitable for treating only skin diseases and superficial infections. But this is advantageous as the underlying tissues are not inflamed. The cases which Fluien treated were mostly cases of inpus. This is a tubercular infection of the skin which acts much like cancer. The skin becomes rough, in d and slowly rots away, leaving small tubercul wart-like projections about the edges of the sore. An-other disease readily cured by ultra-violet rays is psori-lasts, in which the skin becomes scaly and covered with white flakes and which causes intense irritation and itching. Finsen's followers even claim to cure cancer, but this is extremely doubtful, and no authentic proof has been submitted. The application of ultra-violet rays was made in treatments lasting about an hour. It was found that too long continued application inflamed the skin just as exposure to the light of the sun. In effect the inflammation is nothing more than ordinary sunburn

In cases of tong standing disease it was often neces in cases of long standing disease it was often neces-sary to use silver nitrate as a caustic to clean the spot to be treated by the ultra-violet ray. The X-rays were also very useful in cases of deep seated disease as they have so much greater penetration effect than the ultraviolet rave

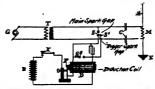

This form of treatment was found to be very effect tive and over 2,000 cases have been treated, of which over 60 per cent were cured. This extensive treat-ment was made possible by State contributions. At first, cases of very long standing and of people of very advanced age, crowded the institutes and the cure of hese was extremely doubtful. By far the most important use of the uttra-violet rays

at present is the use of the light for purposes of sterii izing drinking water. This has reached a high stage of development in France. As early as 1906 Messrs Courment and Nogler began experiments to determine the value of ultra-violet rays in sterilizing liquids by their action. As a stimulus to their activities the city of Marseilles in 1909 authorized an open competitive test of water filters and stertilizers for purifying the

The compensor, which was normany our. The compensor at their own expense a purifying plant capable of furnishing 200 cubic meters = 12.840 gailous of water in twenty-four hours. The appearatus finally adopted was an installation using a rough filter and a sterilizer of the type shown in the accompanying drawing, using a West inghouse-Cooper-Hewittamercury vapor lamp with quartz

tube. The water is run through a cast iron box in the tube. The water is run through, a said troit look in the port which is supposed a questio piecerce; are tunnel to the control of the control off the rave

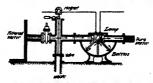

The box lamp is pivotally mounted so as to ellow titting of the tube to start the light. In series relation with the ismp is arranged an electromagnetic centrol of the waste valve as indicated in the drawing. In case the current falls or the lamp goes out, the valve automatically opens and prevents any of the water passing through the apparatus without being sterilised. This is highly important for even a very small amount of unsterlised water passing into the pure water mains would contaminate the entire supply for some sime. With this apparatus it is possible to aterilise 600 cubic With this apparatus it is possible to attentiate 600 within meters (158,800 gations) in twenty-four hours at a cost of about \$10 a million gallons. The water is not altered chemically and the taste and odor is not changed in the least. The importance of this application can hardly be overestimated. In the case of city water supply it is apparent that where this form of apparent

The principle of De Forest's wireless system based on Herts's discovery that ultra-violet rays striking a metal plate ionize the air about it.

is used there is no risk of a wholesale epidemic of typhoid and other fevers. In use for hospitals, hotels barracks, and school buildings this means of sterilization is unsurpassed. In commercial installation, where pure water supply is important, such as breweries, canneries, creameries and prepared food laboratories it

Regarding the effect of the rays upon bacteria the regarding the energy in the rays upon becurs insection has been supposed to be due to formation of ozone, which would then act upon the bacteria, but on the contrary the bacterical action is direct. No osone is formed in the water though the incidence of ultraviolet rays upon the atmosphere causes the formation of ozone. The water thus treated was first tested by feeding to dogs and guines pigs, but no bad effects were produced, and since then, practical use for domestic purposes has proved the water absolutely harmiess. A paculiar fact noted, is, that pathogenic or disease caus-ing germs are killed much more quickly than are the nary harmiess germs. Germs that resist boiling

Courment-Nogier apparatus for use in sterilising water by means of ultra-violet rays.

for a iong time are killed instantly when exposed directly to the influence of the rays. This scheme has been applied as well to sterilizing milk, beer and other liquids, but the apparatus is modified so that a chinner stream is exposed to the rays. All colloidal and sus pended matter cuts off the rays very quickly. The pas sage of the ultra-violet rays through air ionises the latter and forms ozone, which gives the milk a bad tasts, so that it is necessary to pass a current of nitro-gen across the surface of the liquid to shut off the oxygen. This increases the cost above that for sterilised water, but it is triffing.

ised water, but it is triffing.

A However, practical application of this effect is insee in the bleaching of flour. After milling, the flour is all solvely sprinkled down a choice. In this choice is an arc lamp of high power. The onone generated by the ultra-riolet rays from this lamp bleeches the fleier to perfect whiteness. The cost of such treatment is insignificant, and by this means four made of a poor grade of wheat appears as whith as that made

from the highest grade. The flour is the sense and contritive value when so invested that the sense is sense in the part of the sense process of the sense of the arn up, due to the arc caused by making and breaking a heavy high voltage curren

a neary mgn vortage current.

One of the most bold and startling applications of
the use of ultra-violet rays has been made in a study
of minerals, more particularly in determining the elements upon moon, sun and stars. The method pursued is somewhat as follows: A photograph of the moon is taken by ordinary yellow sunlight reflected from the moon's surface, and certain dark apots and other light spots are noted on the surface. Then a photograph is taken by ultra-violet rays alone by means of a quarts taken by ultra-violet rays stone by means or a quartu-lens coated on one side by a thin film of all view screen-ing out all other rays. The contrast is remarkable. Some of those dark spots appear bright and some ap-pear even darker than by yellow sunlight, while some of the bright appear postly dark. This is due to the fact that most substances absorb the ultra-violet rays to a greater or less degree than they do yellow light. By suitable comparison with known substance on the earth it is possible to arrive at the minorals that make up the surface of the moon. This idea is in practical use at the Harvard observatory.

Another use of ultra-violet rays that promises great-Another use of directions rays that promises great-ly to surpass any of the present uses is the manu-facture of chemical substances and compounds. First, is the synthetic composition of rubber. Organic comis the synthese composition of runors. Spans com-pounds that have hitherto resisted treatment except by a very tedicus and expensive process under the influ-ence of these rays, readily assume the desired form and make the commercial manufacture of rubber posand make he commercial manufacture of Pubber pos-sible. However, this is so recent as to be largely in the experimental stage, but on July 16th, 1912, a patent was granted to German inventors, Mesars. Graul and Hauschke, for such a process.

use to which these rays is put is the manu facture of sulphuric acid  $(H_sSO_s)$ . Under the influence of the ultra-violet rays the sulphur dioxide  $(SO_s)$  takes on an additional atom of oxygen and becomes states on an adultodat stop of Osygen and becomes suiphuric anhydrid (80<sub>2</sub>), which in combination with water, forms the acid. This supplants the use of the expensive platinum black, and gives a pure process. Many other uses not as yet of commercial importance

expensive platinum black, and gives a pure process. Many ofter uses not as yet of commercial importance are being developed. But the great value of this form can be readily seen from the above. It takes photo-graphs, gives nummer tan, bleaches flour; ripuns repe-tables, sends wireless telegrams, makes the manufac-ture of rubber heels and automobile tires possible, puri-fice debutions are sensitive. fies drinking water, sterilizes milk, and ages whisky

Before a recent congress of German naturalists and physicians, Dr. W. Stempell described the utilization of ultra-violet rays in studying micro-organisms. By the aid of ultra-violet rays it is possible to discover objects which cannot be seen in an ordinary microscope objects which cannot be seen in an ordinary microscope because of their extreme smallness. With the aid of ultra-rieist rays Dr. Stempell discovered the spore of the dreaded parasite that infests the silk-worm— feat the drauded parasite that infrast the silleworm—a feat which would have been utsely impossible with cotd-naty light. Dr. Stempel suggests that it may thus be possible to discover the microbes of infractions dis-eases of whose bacteriological origin little is known. This accompanying litterstrons, Figs. 1 to 8, show microphytographs of the spores of Nosesies becomes lights; semewhat colliquely to the plane of the micro-scope sides (magnification g. 500 e1). This short quarter century has seen the world-wide acceptance of electrical transportation, the introduction of high-power generation and transmission of electricity, the radical changes in construction due to the use of steel and re-enforced concrete, and is

as sees and re-warorose concrete, and innue able improvements in chemical and allied aris. Perfected during this period were such spech-making inventions as smoote-less powder, high-speed steel, contact method of making sulphuric acid, elsetrolytic refining of copper, the quick-act-ing brake, automatic telephone exchange, centrifugal cream-separator, tungsten lamp, Diesel oil-motor, and Harveyized armor-plate, which changed evicting prac-tices so radically or induced economies of such vast degree as to make it difficult to exclude them from any list except by the adoption of a standard so high as to be

adoption of a standard so high as to be unthought of at any other time.

In making a selection from the bewilder-ingly opulest array of creative activities of the period, only such inventions were included as were most revolutionary in character in the broadest fields, which as churacter in the broadest faults, which af-fected most our mode of Urina; or which opened up the largest new sources of wealth. So weighing the murits of the different inventions, it is concluded that the ten greatest and that, approximated that of mechanism commercial introduction, due to I. Shestric terriess, 1881; [7] shears patient. 1884; [4] generals submitted.

As soon as the last estay for the SCIENTIFIC As soom as the stat easely for the ECENTIFIC AMERICAN'S prize contest on the subject "What Are the Ten Greatest Inventions of Our Time, and Why!" seas received, the Editors cast about for judges who, is accordance with the rules, were to consider the contributions. They were fortunate in securing Prof. B. deB. Parsons and Dr. Gustav Lindenthal, men of wide culture and engineers of wat experience. Their decision is rendered in the following letter:

New York, 17 October, 1913. To the Editors of the SCENTIFIC AMERICAN 361 Broadway, New York city.

861 Broadway, New York city.

Gentlemen: Complying with your request to select from the papers submitted for the Prize Article Contest mentioned in the SCRENTEIR ARMERICAN, 30th August, 1913, we beg leave to report to you the following as our decision:

We do not consider that any of the papers submitted fully complied with the spirit and condimited prevention of the papers and the selection of the papers and the paper of the papers are selected as the paper of the papers are selected as the paper part of the papers of the

We also consider the following papers as worthy f honorable mention, via: "Idline," "Kennebec," Nicolaa," "Spero," "Theta," and "X. P."

H. BEB. PARSONS, 22 William Street, New York Dr. Gustav Lindenthal, 68 William Street, New York.

The cesay of "Esam" (Mr. William 1, Wyme which won the first prize of \$150, is published herewith. The eastly of "Altair" (Mr. George M. Dowe, the United States Patent Office), which won the d prize of \$100, will be published in next tocok's Scientific American. The essay of "Cherry Valley" (Mr. W. C. Cahall), who won the third prize of \$50, will be published in the Scienprise of \$50, soill be published in the Scipper and the state of \$50 and the publication of accepting the publication at accepting intercels by the caseny of "Idline" (Emil Schwitze, Baltimore, Mal.); "Ecomodec" (Louis P. Webert, Bath, Maine); and "Nicolae" (Emil Stoog, St. Nocolaen, Wean, Belgium), St. of vehom received honorable mention. The easelys of "Spero" (Or. Thomas Aplus, Fiorinae, Malla); "Thete" (George S. Clements, London, England); and "X. P. "(B. Rev. Even. Washington, D. C. was this. P." (G. Res Fryc, Washington, D. C.) may like-wise be published in the SCIENTIFIC AMERICAN SUP-PLEMENT provided the exigencies of space will p mit.—Regrous of the Scientific American.

PERCENTHALE (8) linetype machine, 1890, (9) induction motor, 1890; (10) electric welding, 1889.

The date of commercial introduction is held to be that from which orderly and continuous development proceeded. No invention was considered eligible which could not provide subject matter for a patent controlling its practical operation for at least a part of the Such a rule excludes re-enforced concrete, the

development.

Steam Turbine .-- A New Heat Engine

The greatest agency in the service of man is the steam engine. No other device has been so studied, improved and super-reflued. Hut its usefulness reached its ilmits when it failed to satisfy the enormous gre for power demanded in electrical generation and ship propulsion. The steam turbine solved the problem, and the reciprocating engine, which has borne the brunt of the world's work so well during its century's primacy,

has all but been climinated in these two vast fields.

The turbles has effected striking economies in steam consumption, attendance and installation. It has abolished pounding and vibration, eliminated cumbersome and expensive foundations, reduced the space occupied from one to two thirds, and made it advisable to send efficient but older type of equipment to the scrap heap.

Six million horse-power were employed in turbine-driven ships in 1910, and a like amount is used in turbogenerators in this country alone. The days of the re-ciprocating engine are almost numbered—the electric motor is driving it out of the factory and the generation tricity requires turbine installation.

Such is the vast extent of the revolution now being effected in our basic engineering art by the steam tur-bine, invented by Parsons in 1884, but not recognized as a commercially practical proposition until ten years

The Gasoline Automobile and the Change Which It Has Wrought in Transportation.

The inventions of this period which have worked the

most rapid alterations in the more intimate affairs of life are the gasoline automobile and the moving picture. "auto" in this short space of time has developed from a mere experiment to the making of one of our largest industries, has caused the creation of thousands of miles of improved highways, has almost abolished the horse in the cities, has changed to a marked extent the manner of flying of an appreciable portion of our people, and has directly induced extensive and radical improvements in and created dozens of collateral arts.

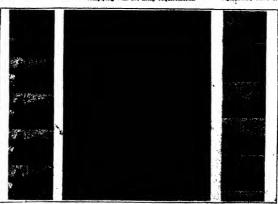

Superficially, the "auto" appears to be the sum a series of engineering developments in which great inspirational achievements were wanting. But no fact is plainer than that its introduction was neither casual nor fortuitous—the whole history of a century's findst-ent but unsuccessful endeavor to provide a practical self-propelled car proves that the success of any type vered requirements would be imthat once ansy Such success did come with the advent of the Daimler or, and not before. The distinctive features of this

motor were lightness and speed, but these were precise-ly the factors that differentiated it from its predece and that prouliarly adapted this engine for its specially designed purpose. As one au-thority says, "The improved engine in 1889 by Daimler was that which really set going the motor-car movement." In that year, Panhard and Levassor Frenchmen, scquired Daimler's putent rights, devised the first motor carringe along present lines, and may be said to be the creators of the automobile industry. In this country, the automobile is making industrial history; the annual output is reaching toward a half billion dallars "nuto" manufacturing centers are growing faster than the beceasing population can be housed, and the value of its than fifty fold in the last cen-

The Moving Pictures .- How a New Art Was Created. The moving picture has

Orville Wright flying at Fort Myer in 1908 and complying with the army requirements.

Orville Wright.

larity has a fored since Shake spear time, its ram

coming more varied and extended. As a factor in of coming more varied and extended. As a factor in semi-cation, science, trade, and in recording current history, it has seen its beginning only, and in its application to amnoement in its higher form we airsendy have a promise of a large and brilliant future.

Thousands of theaters are devoted to the "movies" in this country, in which eighty million dollars are inwested, producing an annual revenue fast approaching three hundred million dollars. The whole world is levised upon to "stage" the play, history and travel is levised upon to "stage" the play, history and travel is ualised, and the obscure processes of nature explained and analyzed.

and analysed.

"The "kinetoscope" of Edison "was the first commer-cial appliance to show pictures in natural movement," although he owed much to the Eastman film and price investigations. As with the automobile and aeroplace, great credit must be given to French promoters for first ving its possibilities on a marke

The Aeroplane.-The Realisation of an Age-leng

Next to the philosopher's stone and perpetual motion has man's attempt to fly been the object of most per-sistent pursuit. No other problem in the realm of invention has caused such heart-breaking discourage-ments or called for such sacrifice of life. In spite of authority, however, the quest for the flying n was not chimerical, although it seems but was not chimerical, although it seems but yester-day since success capped the efforts of the Wright

Although the aeropiane is radically transforming military lactics and as an engine of war cannot be ignored, it presents the least commercial utility of all the inventions considered. But because it is in many respects the most radical innovation in the whole history of locomotion and because the perfection of this device opens up possibilities dazzling to contemplate, present utility must be ignored in appraising this strik ing accomplishment. It is only necessary to imagine a condition where frontiers are climinated, valuable way unessential, and fortresses and battle-otent, to realize the overwhelming revolution rights of way up which will come with the perfecting of air navigation-an outcome by no means beyond the limits of possibility.

ss Telegraphy, the New Meuns of Communication

If the aeroplane is the most spectacular achievement of this age, wireless telegraphy appeals most to our magination and dramatic sense. Its importance and significance however are in direct proportion to the

hold it has on our interest. The scheme of transmitting intelligence was never con plete so long as ships at sea and remotely situated stations could not be communicated with. "Wireless" supplied this 'missing link" and made inreommunication as universal as the world is wide. In the short fifteen years since its introduction by Marconi, wireless apparatus has be come nart of the equipm every modern sea-going and naval vessel, has been placed in hundreds of Government establishments and downs of relatively inaccessible at a-tions, has become an important factor in military mayal operations, and, most important of all, has robbed the sea of its terrors and saved thousands of lives through its operation. Rapid as has been its growth, it is but in the infancy of its de-velopment and usefulness and promises a cursor in over communication quite as a poblicionali postali ·马克克斯·斯克克克·西克克

#### The Induction Motor of Nikola Tesla and How it Revolutionised Power

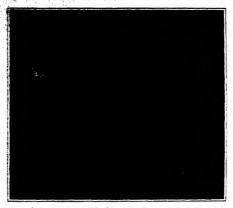

Ninety per cent of electric current generated is alternating because larger generating units can be utilized and the current more easily transmitted. The induction motor, constructed by Tesia in 1988, and independently suggested in principle by Ferrari, was the first satisfactory medium to transform this current into power.

This epoch-susting invention is mainly responsible for the present large and increase in the present large and increase it is working a revolution for working a large and comfort in the mill, factory and working, in making the motor an individual power unit, it has made power arrangement elastic drawing upon energy only when needed and applying it directly only where wanted, and has noblabed lies shafting and beilink. It conserves theiry to sixty per cent of the energy formerly wasted in uselessity whirting line shafting, it aswes overhead space and increases productivity by making the shop lighter, after, cleaner and less missy, and so well recognized are these advantages that establishments in every lig industry are installing these motors as a measure of accounts anti-deferment.

#### The Linotype and the Spread of Knowl-

The "art preservative of all arts," in the department of composition, remained the same in all its fundamental particulars for four centuries after Gutenburg first set movable blocks to form a printing surface. The most intricate devices ever evolved and the most inguelous of forts are expended, falled to successfully supermede hand composition until Mergenthalier's linotype established for feasibility about 1890 and entirely overcame public skepticism and inertia a few years later. It is smough to say that an opperator can set from five to ten times faster than the average hand composition that that the type composed always presents a brand new face, that the coat of foundry type and surillary parapherosita is dispensed with, and that distribution of the type matter is abolished, to recognise the breadth and theroughly revolutionary character of this invention, and to appeads the way werey newspaper and large printing plant in the world has installed meschine composition.

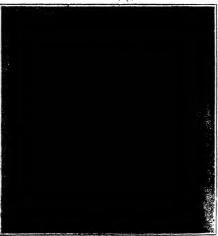

#### The Electric Welding Process of Elihu Thomson.

A typical central station in which Parsons turbines are used to drive electric generators. The portrait is that of the Hon. C. A. Parsons.

The electric furness is radically transferming the steel industry.

The electric walker of Either Theorem

The muchine bers shown will wolf five dissided sight bainfo in an hour. It takes only a few ecousin to mike an shortly wolf. A body survent of electricity at a low voltage this gained through the abusing sadis of the motal pieces to be welded, thereby generating family at the paints of contact, willis at the same time preserve is applied to force.

brome, east tron, etc., but different and wedtably antaconistic metals can be united in a wild union. Simpes so intricate as to be beyond the expacity of welding by any previous device or process, or which could only be joined by rivering, are readity united by the electric welder. The applicability of the process to practically all metals, the disposing of heavy pressures, the surely and swiftness of the resuits, and the economy and elemilius of its working, made it a startling successful proposition from the very first, and now its application is as broad as the metal-working industry field.

The Inventions of most for-cerching effect have been actived multive in the few departments of power, communication and production. Modern civilization received its impense from the inventions of the steam eagine, howematic and telegraph, and the Bossemer converter, typifying these three departments of the inventions selected it will be observed that seven full within these activities. Of the remainder, it is sufficient to say that for the first time we have means to visually transcribe animated life, and have seen hand meliods in two ancient arts superseded by mechine operation.

Of all the great achievements of this period, these ten have been chosen because they are pioneers of the highest order and have been most revolutionary in the most notent fields of service to mankind.

#### The Ten Greatest Inventions

WHEN, a few months ago, the Scient Tipic American offered prizes for the three least essays on the ten genetics patentiable inventions of the just twenty-live years, we had no idea that the question would be a very difficult one to answer. It seemed certain that the inventions could be chosen which would stand out prominently above others and which would hold thoir pre-eminent position with coording argument. In response to our offer essays came in from all parts of the United States, and from almond as well. Among the essays receiving honorable mention, as published on another page, will be found one from England, one from Belgians and one from Matta. It is interesting to note also that several of the essays came from women, showing remarkable interest in invention among the gentler sex.

When the casays were opened, the lists showed a surprising diversity of opinion. No two competitors selected the same set of inventions. In fact, only one invention, that of Wireless Telegraphy, was con-ceded ununlmously to belong among the ten greatest The vote on Arrophnes almost unanimous. But beyond that there not the slightest trace of unanimity This result was, to us, surprising indeed, In the conditions of the contest we had stated that greatness would be measured in terms of practical success and general usefulness to mankind; we limited the contestants to machines, devices, and dis-coveries commercially introduced in the last twenty-five years, and inid special emphasis on the fact that the inventions must be patentable, although not neces arily patented, stating also that the pat-ent might antedate the twenty-five year period provided the commercial introduc-tion of the invention took place within the specified time. With these simple conditions governing the contest, it seemed strange that the contestants could agree on only one invention. But when the mat-ter was put to a vote among the Editors of the SCIENTIFE AMERICAN, we ourselves could not agree on more than half a dozen Arguments n-plenty, and good ones too, could be put up in behalf of a score or more of inventions. The matter proved so interesting that we called for a general vote from our renders on the subject. A dozen essays were picked out at random and these were found to contain forty different subjects

The list of these subjects was published with our call for votes, merely to show the disagreement on the question This (Concluded on page 150)

A STATE OF THE PERSON OF THE P

#### A Multiple Disk Glass Cutter

FOR more than four thousand years there was no I other means of cutting glass than with the diamond, and it was usually done with the chip diamond. It was, however, very effective, but it remained for an American to invent the little wheel or disk approaching the hardness of the diamond and taking its place for doing this work

Among the several types of wheel glass cutters m factured, one of the most unique is a multiple disk cut-ter with a turret head containing six wheels. These small wheels or cutters are placed around the peri-phery of a larger disk which is pivoted on one side of the holder. One wheel after the other may be brought into the position for cutting by simply turning the turret head by loosening and tightening a screw.

the turret head by loosening and tightening a screw. In order to prevent the cutting edges of the disk from becoming rusty, a disk of absorbent material is placed on one side of the turret head in such a manner that it continually rubs against the upper edge of the disk which is in the cutting position. This absorbent material is filled with oil which keeps the wheels clean and free from rust.

#### Lessons of the Disaster of the "L. IL" By Carl Dienstbach

THE most advanced of all dirigibles, the giant Zep poin "I. II.," completed for the German navy, has shared the fate of one of the crudest early attempts at airship construction—Severo's "Fax." In other words, the "L. II." exploded and burnt in the air and everybody on board was killed. One man, in spite of terrible burns, survived the fall (of 900 feet) for several hours.

No general conclusions can be drawn from this latest No general conclusions can be drawn from this latest and most terrible disaster sustained by a gen-inflated ship. Nor is the conclusion justified that gasless acropianes are safer. If a comparison is made between dirigible and flying machine on the basis of safety, very hour spent in an inflated dirigible must be count-ed against only the actual flying time of aeroplanes. On that basis the comparison will be in favor of the dirigible Aeronauts are not afraid to ascend in a spherical balloon filled with inflammable gas. Statistics covering a century and a quarter have shown how slight is the danger of explosion if reasonable precautions are taken. When Severo's airship caught fire, a commission of French engineers decided that it was due to confined spaces within the structure, where a stagnant mixture of air and gas might collect like so much gunpowder. That explosive mixture, once ignited, is worse than so much dynamite. To the ignition of such a mixture the accidents to the old Severo and the latest Zeppelin are due. Gas alone is as harmless as so much flour. An official rule was laid down at the time of the Severe inquiry that no design with such confined spe severo inquiry that no design with such contined spaces should be tolerated. This rule was easily observed by the old, slow "full rigged" ships, with the car hanging far below, and a goodly draft of air automatically sweeping the intervening space.

Sweeping one intervening space Curlously enough, it seems to have been progress in statisting staunchiness and speed, that eventually brought about a design that embodied the very defect that caused the destruction of Severo's dirigible and made it models for membering seems. made it possible for an explosive mixture to accumulate one quantities

Close proximity of motors and gas bags is highly desirable and even necessary in a very fast and strong dirigible. However flimsy the fabric may seem, it is dirigible. However filmsy the fabric may seem, it is just as efficient in keeping the gas out of harm's way as the plates of a gasometer. The fabric of a Zeppelin cannot be torn unless the frame and the netting which strengthen it break first. It cannot retain the gas indefinitely Still, so little filters through, that a candle can be burned three inches from an inflated balloon, as long us the gas remains at constant temperature and pressure. Gas never becomes dangerous upless it expands from heat or lowered uir pressure, and, over-flowing the balloon through the safety valve, is not in-

Multiple disk giass cutter. The insert shows the turret head and its wheels in two positions.

stantly diluted with enough air to make the mixture bustible

onfined spaces within the structure of an airship are harmiess as long as they are swept by a blast strong enough sufficiently to dilute any amount of gas which may there collect

"f. II." had literally a tunnel running within the hull. Within that tunnel gas leaking from the ball in many compartments could accumulate and mingle with air. She should have had a blower to drive out the hydrogen that had leaked out, or at least to dilute it with an enormous quantity of air. Indeed, she needed

A mine rescue telephone equipment. The transmitter is strapped against the throat so that the rescuer talks, not with his mouth, but with his

a blower as badly as a cosi sains. "Gas" might be expected every time the ship rose or was exposed to the

A blower would not detract much power from pro-pulsion, because it is not needed while the aidp is under full headway. The ordinary ventilators of a steamer become very efficient when they are applied to a speeding dirigible, because the latter gets the wind while the airship is at rest, the motors, instead of run-ntug empty, should drive a safety-fan. Any confined

ces must in addition be sealed and spaces must in addition be seeind against away man, simply by providing such must refer them. A Mine Rescue Telephone Equipment THE development of practical telephone significant for mine rescue work to supplement the surplement a for mine receive work to suppessed the exygen appearation now in almost universal use search; a great step forward in providing ways and means for preventing the great loss of life which, in years past, followed every mine disaster. The great value of the exygen every mine disaster. The great value of the oxygent helmet, which permits its wearer to calter a nine and remain in the presence of snoke and poisonous gases for hours at a time without danger of being overcomes, has been evidenced by the hundreds of lives which have been saved through its agency. The iron box mati-telephone has also proven to be of insettinable service in protecting lives and property. In fact, the laws of a number of fattes in which mining operations are conducted, include statutes making compulsory the use of telephone magnerround. of telephones underground.

There has been lacking, however, until very re means for keeping the advance or rescue party in the mine in constant communication with the rear party at the entrance of the mine. The need of this was ad at the entrance or the mine. The need of interest of vanced by the United States Government Bursau of Mines, as well as some of the large mining interests. As a result it is now possible to obtain a light service-able and simple telephone equipment which will mest all the requirements of this unusually severe class

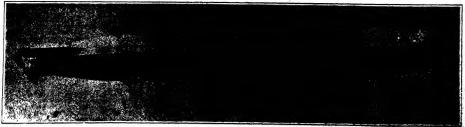

One of the first difficulties encountered in the develop-ment of the telephone equipment for the helmet man was to devise a transmitter which would not interfere With the oxygen belmets and other with breathing. With the oxygen helmets and other types of breathing apparatus in use for rescue work, the mouth is covered in such a way as to prevent its use for talking. This led to the design of a transmitter which is fastened to the throat by means of a pigekin harness and transmits speech on the principle that the vibrations of the vocal cords are transmitted through the throat walls and will in turn act upon the diaphragm of the transmitter. It is essential that the transmitter be held firmly against the skin, and for this purpose a soft rubber cup, which will conform to the curves of the threat, is provided where the mouthplese would ordinarily be placed. It has been found by laboratory tests and tests made at the Bureau of Mines in Pittsburgh that the throat transmitter will transmit

protection of the street transmitter will transmit speech practically as well as the ordinary telephone.

Attached to the same harness with the transmitter is a water-case receiver equipped with a leather head hand to clamp it famly to the ear. The head harness, with its receiver and transmitter, is so constructed that it will not interfere with the operation of any of the various types of oxygen apparatus on the market. The ead equipment, furthermore, is extremely light and oes not in any way inconvenience its wearer.

The telephone apparatus used by the directing party at the outside of the mine is a standard switchboard set consisting of a chest type transmitter and head hand

A "Safety-First" Lescon.—In a recent publication by the Pennaylvania Railroad, whose object is to promote "safety-first" principles among its employees, we note by the Pennayivania Raliroad, whose object is to promote "assley-fure" principles among its employees, we note two illustrations, each showing a man seated on the wooden shield oversing a third rail, and engaged in some repairs or inspection of a freight car. In the first view, entitled "The Wrong Way," the man is seated directly upon the third rail structure. In the second illustration a large rubber blanks has been thrown over the rail to protect the man's body or his tools from easing a short creasis.

The Zeppelin airship "L.IL," which exploded and burned in mid-air, killing twenty-eight men.

### The Heavens in November

#### Three Interesting Comets Now in the Evening Sky

By Henry Novie Brosell, Ph.D.

CARADIS anothrow to be the principal especies of inwiscose this mouth—own move so than last, for three
sit cans are visible (with the thistoppe) in our evening
sides, and two of these are of unismed intersect.

"Metach?" count, of which we spike last month, has
been a conspicuous telescopic object throughout Orthere, meaning right across the dreumpolar sky. It is
now creeding from us and from the frum, and rapidly
growing fainines, but is spill visible lan a small telescope.
According to an aphenesete compressed by Prof. Crayrion and filling key at the University of Coldifornia, the

Levy at the University of Califor of this comet should be as follows:

November 15... 20 hours 46.9 minutes November 80... 20 hours 46.9 minutes November 80... 20 hours 52.9 minutes + 2° 18' The brightness diminishing from 1.3 times that at discovery at the beginning of the month to 0.3 at its end, so that by that time it will be a practy faint object. The comet's orbit, according to the best data so far

The comet's orbit, according to the seem to published, seems to be nearly, if not quite parabolic, and hence it must be very long since it last visited the

able object, but is unfortunately too faint to be observable object, our is annormatical too maint to or observable with small telescopes. There is no doubt now that its critic is cliptic, and its period fairly short, the pre-liminary computations of various astronomers giving periods of from nine to twenty-five years. It syill not perions or from hine to twenty-new years. It syll not be possible to determine the exact period usualli observations covering a much longer are of the orbit here been secured, but the congrutations agree in showing that the conset was in perihelion at the beginning of Reptember, that the inclination of the orbit is small (about 14 degrees) and the motion direct, and that the perhelion distance is shout one and one half times the certify distance from the Sun.

It is not surprising that this comet has not be observed at its earlier return, for (as the diagram pub-lished last month clearly showed) the present appear-ance was so timed that the comet came about as near ance was so timed that the comet came about as near as possible to the Earth at the same time that it was nearest the Sun, and so appeared as bright as it was nearest the Sun, and so appeared as bright as it was nearly to the same time to seem. Even so, it was only of the magnitude 11.5, and is now a good deal fainter. If it had come along six months excite or later, when the Earth was on the opposite side of the Sun, it would never have appeared brighter than the fourteenth magnitude, and would have almost certainly excepted distinctions of the sun of th

emarkable thing about it is its tele Are most remarkace thing about it is its belescopic appearance. Frof. Altient of the Lick Observatory (a very experienced observer of comets) says concerning this: "In the monilight the object showed very little resemblance to the ordinary comet. It

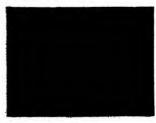

had the appearance of a star of magnitude 11 or 11½, with no more than the merest suspicion of nebulosity. Indeed, it was only detected by its motion." Later, on a dark sky, "a faint brushy nebulous extension, like a short tail, was seen to extend three or four minutes of arc to the southeast from the nucleus." are to the southeast from the nucreus."
No wonder that Prof. Aithen declares, "I have never seen an object like it." It will be of great interest to learn just what the character of its orbit will finally prove If the shorter of the computed periods is correct, it will have almo many points of resemblance to an asteroid

many points of resemblance to an asteroid as to an ordinary cound:

The ophomeris now at hand for this counct runs out in the middle of October, but by approximate extrapolation if would appear that on October 30th its position, should be in 28 hours 30 industes jl. A. and 35 degrees 17 minutes, nowth declination; and its motion a little seat of noethward, at the rate of about eight handsome of any per day. It will however. he of the property of the property

ward, at the rate of about sight indicates of any par day. Is will, however, he of he upon at all for the omnature with a must insert manner to the part of the pa

was dispossed on July Seth, 1600, by Westphal at Ofcitions, and observed upth January 11th of the following year. When speace the Barth it was easily visible to the naked eys, and had a tall shout a decree in length. The observation accessed at that appartion left no doubt that its orbit was an ellipse, and its od about sixty years. All the available data were period acoust many years an use a variance out of the rediscussed a few years ago by the Austrian astronomer Hagtel, using all needful redocuments of calculation, and allowing for the perturbative effects of the attractions of Jupitar and the other planets. He con-

The erbit of Westphel's comet.

cluded that the period indicated by the observations as most probable was 61.71 years, but that any period within six months or so of this might be as without doing violence to the observational data.

without comp violence to the observational data. For a year or two back, Hnatch has published "search ephamerides," telling "when to look for the comet on various hypotheses regarding the actual length of the period. As soon as Delavan's discovery was announced, the was seen that his comet was in the right place, and when it appeared that it was moving in the right direc-tion and at the right rate, there remained no doubt

An independent calculation of its orbit, made at the An independent calculation of its orbit, made at the University of Culifornia on the basis of the first week's observations, assuming only that the period of the orbital motion was known, yields values of the other elements agreeting closely with those of the comet of 1802, and shows that the exact length of the revolution just completed is 61.118 years, the comet returning to partision on November 20th.

The orbit of this comet, with those of the planets

from the Earth to Uranus, is illustrated in the an nexed diagram. The comet's orbit is supposed to be in the plane of the paper, and to be seen "in plan." while the orbits of all the planets are seen parily edge wise, and hence appear elliptical, though really almost circular. They actually lie in a plane inclined about 41 degrees to that of the comet's orbit, so that the parts of the orbits drawn in the diagram with full lines must be supposed to be above the paper, and the dotted

With this explanation it becomes apparent that the et's track passes very pear to those of Mars and Jupiter, and fairly near that of the Earth, and that it can never come at all close to any of the other planets As in many other cases, the close approach of its orbit to that of Jupiter is probably by no means a matter of chance. It is well known that if a comet passes near this great planet, the influence of his attraction may radically modify its orbit, changing it from the origin parabola into an ellipse, if Jupiter's attraction slows the et's motion, or into an hyperbola, if it accelerates it

After such an encounter, the comet will pursue a new course, which, since it passes through the place of meeting, must of course come close to Jupiter's For many revolutions the comet's track may now anffer little change, if it does not pass the critical region at the same time that Jupiter does; but the tell tale nearness of the orbits will preserve the history

It is probable that most, if not all, of the county of short period got into their present orbits by this process of capture; and in the case now under consideration or capture, and in the case now inter consideration we can say with some confidence that Jupiter was the capturing body. Mars, though it may sometimes come almost as near the comet as Jupiter, has so small a mass (only about 1/3,000 that of Jupiter) that its attraction is relatively quite ineffective.

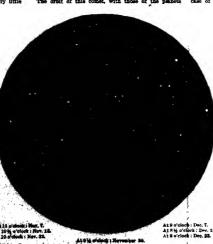

Of course, the encounter which originally changed the comet's orbit may be repeated at any return, and sooner or later is bound to be rejeated. The two bodies, some time or other, will come to the junction point almost at the same time, and the comel's orbit will again be greatly changed. It is practically an even chance whether the comet will be accelerated— making the orbit much bigger, so that it returns at longer intervals, if at all—or retarded, in which case ellipse again grows smaller, and the period si

Westphal's comet will not come at all uncomfortably close to Jupiter on this return, nor did it at the last. To attempt to calculate what happened longer ago by carrying back the present period would be illusory, for, even if the comet did not come very near one of the great planets, their attraction (as in the similar case of Halley's comet) may cause the intervals be-tween returns to vary by many months

comet itself is not a large one and would be a faint object if it, too, was not favorably placed with reference to the Earth. The various estimates of its brightness made soon after its discovery indicate that the central nucleus was of about the eleventh magnitude, while the whole brightness of the head was about the eighth magnitude. Theoretically, this the comet was at its nearest to us just after its discovery and is now slowly re-ceding. But it is still approaching perihelion, and the light of a comet usually increases rapidly as the Sun's rays act on il with growing intensity. Toward the end of November, the conditions are al-most as favorable as they were in 1852, when the comet was about of magnitude 414, so that it may become visible to the naked eye. In any case, it will be a pretty object in even a small telescope. Even at the end of September, it showed a bright, round coma, and a tall which could be followed visually for a degree or more

From the ephemeris published by the workers at the University of California, the comet's position will be as follows

NIGHT SKY: NOVEMBER AND DECKMBER

#### The Blowing Up of Gambon Dike

Plooding Calebra Cat With Water from Gaten Lake WHEN the Pausna Canal is opened for traffic its adipping will pass from ocean to ocean through a fresh water censi, formed by the dumning of two rivers, the Chapter on the northern side of the contineutal divide, and the Rin Grande on its southern side The waters of the Affantic will bever, as is popul surround, minute with those of the Pacific; fee although the canal will serve to connect the two on by reperiting the respect of shinging from the one to mit-restor protions of the cenal, one extending for sever uslies to Gatus lorks, on the Atlantic side, and the other, on the Pecific side reaching from Minuform er is distance of 8% miles to deep water in the Parific. The intervening \$5 miles will consist of fresh water. If it should be decided he the far future to cut down the canni to see level, sait water would then he free to flow from one ocean to the other

The thirty-five mice of fresh-water canal or of two lakes. The larger, Gatan Lake, bying to the merth of the divide, has been formed by the ere of a dam at Gatou. It will be maintained at the detion of 85 feet above sea level by the continu eta infor of the Charm Elver, whose waters will been elevely to the Atlantic, part of them finding their way through the looks, part of them over the salilway in the center of Gatun dam, and a considerable purties being lost by emporation from the far-spreading sur square pulles) of Gatun Lake. At the southerir end of the take in the nine-mile Colabra out through the divide. The water le this cut will be at the same jees no the lake, and this level terminates at the Pedro Migeet locks, through which shipping will be lowered 40 feet, to enter a small lake formed by damning the ade River. The ship channel through this lake is about a mile and a quarter in length, and at the tiberly end it egiers the Mirafores locks, in which ships will be inwered to the level of the Parife O The Rie Grande River will continue to flow to the Pa effe through the lake and locks or over the Mirefores

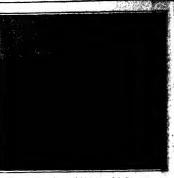

As everyone known the beaviest work of excavation eets done in cutting through the continental divide at Quistra. Work on the cut was began by the French on Jacoure 50th, 1882, when the following cable was sent from Panama to the Bulletin du Canti Inter occasions, which was published in Parts by the French "The first work on the great cut of the maritime canal was formally insugurated to-day in some of the distributes of the State, the leading citizens of the city and the great amenitage of the people. The first iconscitive has arrived at the newly opened acceptation. The city of Panama is celebrating the exect with a great fate.

During the intervening thirty-two years, about 100,-600,000 cobic rands of material has been taken from the great executation; and the practical completi the work was rejeitabled at 2 P. M. October 10th, when Wilson in Washington threw a switch which, threach the medium of the telegraph and cable lines. touched of a blast of 40 tons of dynamite, and made a breach in the Cambos dike, which during the progress f the excevation had served to keep the rising waters of Lake Gatun out of the est.

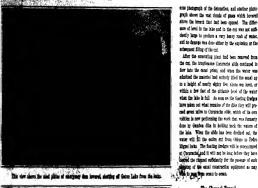

The Chapter Elver, which in the rainy season is entitied to finds of great magnitude, flows in from the west and interaccia the line of the canel at the northaris end of Culeira cut, where it swings to the north on its way to the Atlastic Ocean. On the southerly adde of the river, a massive embankment of earth was built across the canal, and raised to a sufficient height to pravent its being overlopped by the beariest fi the Chagres. I'mder the protection of this dike, the steen shorely, of which at one time there were as many

When the Gambos dike was built, means laid to be posited for getting rid of the drainage in the nin-nilo length of the cut. This was done by laying four 28 Inch iron pipes through the bettern of the dike, and building a remitty piece to draw the water from the cut and discharge it late the Chagres River on the opposite side of the disc. When the exercition of the out was practically completed, and the stoom abovels, locountives, and dirt trains had been removed, together with the tracks and various equipment, the first stetoward filing the cut with water was to open the dreinage pipes and allow the water to pass into th cut from the lake. This was done to provide a cut on the laner side of the dam and localize the effects of of the expiration. Over one thousand holes were defined in the dike and each was loaded with from eighty to one intuited pounds of dynamics. Many a hig blast had been set of during the construction of the canal but this one, consisting of forty tree of drammite, was the innest

eous photograph of the detonation, and another photograph shows the wast clouds of gases which herered above the breach that land been opened. The differsace of level in the lake and in the cut was not suffclearly large to produce a very beavy rush of wat and no demage was done either by the excitation or the seat filing of the cut.

After the excavating plant and been removed from the cut, the troubleaume Cururacha slide continued to fow into the care) prism, and when the water wa admitted the materies had controly alled the canal up to a height of nearly eights feet above we level of a few fact of the ultimate level of the water when the lake is full. As soon as the firsting drades staken out what remains of the dike they will proreed asses triles to Operatories slide, which of its out ion is now performing the work that was formerly done by Gambon dike in holding back the waters of the lake. When the aide has been dredged out, the water will fill the eating out from Object to Point guel locks. The floating dredges will be exceed rated at Cocuracia, and it will not be long before they have their the channel sufficiently for the passage of such

#### The Channel Tunnel

T the first France-British Tearing Congress, held Ast Loudon, Barro E d'Erlanger read a report be fore three hundred members upon the present status of the proposed Chappel turnel. Speaking first of the ory of the formation of the first junnel company is 1878, soon after the difficulties of a diplometic order had been overcome, he then referred to the projects of the treasur content. Construction work and excesse of the tounes will be divided into two equal ports. The Exclish and the Prench concentes will thus be rectified to balld about 12% miles of tuncel and to furnish a capital of \$40,000,000. He then dwelt upon the advantages which would be afforded by a tunnel con France and England as remove touring and from a rial and military standpoint. Denger to Eng land from an investor from the Continent, which is one of the male objections to the enterprise avoided by establishing first around the English en create, and also by taking the proper measures of construction so as to not the tunnel out of use in a few be to fill up the tangel with weter. The project is one of view, but also has a wider some than more terrolary two nations

#### The Chronology of Aviation

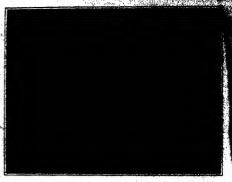

THE SOMETHIC ANGRESS has received from Mr. Hudesu Maxim and Mr. William J. Hammer a limited number of the reprints which they have just issued of the very complete "Chronology of Aviation," ariginally prepared by these gentleman for the World Almanac of 1911. The data embrace the essential facts relating to acrial progress. In eddition to a abort his totical released, one finds berein taking giving addition recrets, speed records, quick starting and slow-speed inger extraing, English Chausel and other over-water flights, erose-country flights, soluble distance and duration flights, etc. There are also establies relating to accidents and data relative to scherical and diziglate bathoose or alrelatos, etc. Of no email interest ers the tables riving the most important fights of the Wright brothers. There are doubtless many readers of the Acustime Authors who are much interested in this subject and who would be glad to secure a copy of this interesting brochare. They can do so by applying to the Aeronautic Editor of the Scientific AMERICAN SET Reseducy, New York

## The Principle of Reversal

#### A Suggestion For Inventors

By Henry Harrison Suplee

It is beginning to be understood that one of the greatest methods of conserving human energy and of using
it to maximum efficiency, lies in the employment of
methods and spiparatus for enabling the skill of the
trained man to be used repeatedly by others who are
sees skilled; or even by the employment of wholly
inatimate machinery. This is only an extension of the
treamendous step which was made when the discovery
of writing, and its follower, printing, enabled the experiences of men to be recorded and accumulated; but
it includes also a discovery, much more recent in point
of time, that the most efficient method of recording is
that which, by the operation of reversal, may be made
to repeat the recorded operations indefinitely.

Although this idea of making records in such a maner that they may be used to repeat the operations which originally produced them, has been known for many years, its practical applications have been comparatively recent. Preceding such automatic methods, there appeared the germ of the process in such devices as the musical box, in which pins, pinced upon a revolving cylinder, enabled nelodies to be produced repeatedly. Similar devices are found in certain tools, in which hearfully formed canns are used to permit a definite sequence of operations to be conducted according to a predetermined plan; while the operations of the perforated cards of the Jacquard loom, and of the various devices for physics upon the plane, by means of perforated rolls of upper or metal, are well known.

ased rous or jusper or metal, a new with flown. In most of these devices, however, and of those based upon them, the original record is made by carefully operated tools of special decay beforehand, but even under such conditions, they are of the utmost importance as indicating a principle which should be more fully appreciated than it now is. The true method for ouising the skill of the trained man does not lie in employing that no do over and over again the things which he can do see well; if their in certain glass skill recorded upon such aprecial pieces of mechanism as can them seen only one of the condition of the seen of the condition of t

The principle of inversal, however, extends still further, and makes the original record its own translator. A number of yours before the invention of the phonograph, there was decised an ingenious maching, invested by M. Leon Sect., and called the phonograph very much, except that the recording stylus was a stiff birdle and made its record upon a cylinder which was covered with a coating of lamphiack smoke. When any spoken or sung sounds were delivered into the funnel, the stylus diade a record of undulating lines upon the smoked surface of the revolving drum, and

numerous ingustoms and partially successful attempts were made to translate these waves into the anomals by which they had been produced. Success we extincted, however, only when Ridmun applied the principles of reveals, and made a machine in which the indontations in a recording cylinder were made to reproduce further than by which they had been originally produced; thus entirely similarities any intermediate process of translation. The detailed operations by means of which the original sounds, mechanically intermediate process of original sounds, mechanically intermediate in the original sounds of the control of

the modern principle of reversal.

In the case of the mechanical apparatus for reproducing music upon the piane or organ, a similar principle is being irrowled. Instead of making the record by a mechanical transcription from the written sheet music, it is now possible for the musician to perform upon a recording instrument, and the marks than inpressed apon a moving strip used only to be cut out to canable any player-machine anywhere to reproduce the original, record thus made.

the original record thus made. One of the most extensive tilbatrations of this principle of reversal now in existence appears in the case of the chresstormph, or mortapeletters metaline. Here a number of trained performan, with all increasing no execution, are employed, at a very considerable expusse, to produce the cristians record; but once produced, the may be repeated indefinitely, with every detail of movement, factal expression, and even coloring, in as many places as may be desired, with no further effort on the part of the original actors, who, in fact, are thereafter occupied in producing other tilms, and in doing once for all, things which are thou capable of repeating themselves indefinitely thereafter.

We see here the possibilities of the principle of reversar for the conduct of the world of the w

The modern system of scientific meanspanent recognizes this principle, in a crute and histind way, by the employment of a planning department, of which the function is the preparation of instruction cards and information, to be closely followed by the workman to candle maximum production to be realised. The workman being stimulated by a wase system based upon productivity, and raided by the instructions of the planning department, is thus employeed to be eached to attain maximum efficiency.

It has feen remarked that such a system makes of the workman nothing less than a meckine, and this being the case, it remains to push the method a little further, to its parfectly legitimate conclusion, and make it possible for the planning department to reduces the interrections to a mechanical record which, when placed in the tool, in a manner similar to that followed in the look, in a manner similar to that followed in the Jaquard loom, or the monotype composing machine, shall proceed without any human supervision whatever. That this can be done must be conseded, almos it is reduced that no machining operation is so complicated, either in sequence of movements or in timing, as it found in an elaborate motion mustal composition. Furthermore, it is possible to speed up the performance of a mechanical record to a rate for higher than that at which it was originally made, the limit in this case being, not that of the workman, but of the juestical and frictional resistance of the machine. When a number of machines are to be employed in making identical objects, it is entirely possible to use one master record or all, using duplicate records for the serveral machines, or, by electric or presuments communication, employing one record to moveme all the machines.

objects, it is entirely possible to use one master record for all, using duplicate records for the serveral machines, or, by electric or pneumatic communication, employing one record to govern all the mischines. In the production of a master record by the skill of a trained workman the time employed in making the original is wholly secondary to its perfection. A nam may well spend hours over the pneumanet record of a few movements when he knows that it is to be resproduced precisely thereafter by hundreds of machines at speeds far exceeding the possibilities of direct humans control.

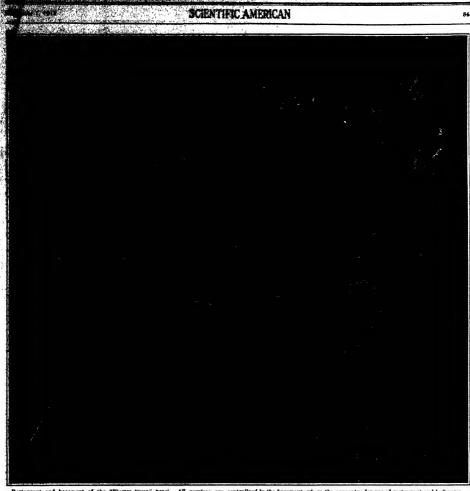

himani control. Following out the principle of reversal, however, the apparatus upon which the skilled operator is employed, should contain which the skilled operator is employed, should contain which the the recording mechanism, and thus there may suppear a new system of machine tools, consisting of a single master record-making machine, to be operated at slow speed by a skilled workman, this apparatus being employed wholly in making records to be translated by a battery of reproducting machines engaged in product's work. The master machine should produce a parfectly finished piece, being governed and controlled by the trained operative, and run as slowly as may be necessary to insure perfection in the product and in the accompanying record. The reproducing tools, once appoiled with records, may then be driven at queets limited only, by mechanical considerations, such as-sigh sensonit of gover required, the resistance of the metarial emptoped, and the inertia effects of meving parts.

the resistance of the metacial employed, and the insectin effects of moving parts.

There is no more need for the skill of a man's hands to give with him than fare the printed record of his foughts to vanish from the partned record of his earth. The movement of the hands, are well as the word spoken by the lijks, may bisoness as effectively recorded for future service himselfer he julie written word or the unitsed need.

The second

Restaurant and basement of the "Electro-Fura" hotel. All services are centralized in the basement, where the apparatus for use of restaurant and bedrooms is conveniently arranged for supplying any guest by pressing a few electric buttons.

#### An Electric Hotel in Paris By Juoques Boyer

M GEORGIA KNAP, the inventor of the electric house which was described in the Schenipiro America at December 4th, 1909, proposes to erect, in paris, a hotel, which will be a marrel of electro-

mechanics.

In this hotel, for which the name "Electro-Feria" has been chosen, all of the services are contralised in the beamont. Here all of the spractice required for the agentice. Here all of the spractice required for the agentice of the restaurant and the bedrooms is arranged an oneastemisty that fits agentue rean promptly expert the needs of any guest by pressing a few electric buttons. There or four misuple are occupied by a next of negroing a prescript mitten. There are four misuple are occupied by a next of negroing at prescribes the the necessing real to a page 1000 per present the four the prescript of the prescript of the necessary "In this hotel, for which the name "Electro-Feria"

and shutters open and flood the room with light. The top of a chiffonier, placed beside the bed, turns and extends itself over the bed to form a convenient table. The breakfaxt and the letters appear on the chiffonier, and, in less than a minute, all of your desires are satissed, for your room is connected directly with the base-ment, where the operator has at hand the means of furnishing everything that you require with a minimum

meets, where are operator are guire with a minimum of delay and exertion. The rectangust of the hotel is served in the same manner. Eachs small table, for two or four persons, is provided with a dictagraph, which is placed in the lamp stade. You touch a button and a voter from the lamp stade. You touch a button and a voter from the lamp stade asks what you wish. You give your order in a loud vote, without putting your mouth to a telephone. A directed platter in the center of the table situs and presently re-appears, ladon with this hope you have ordered. As some as you have helped yourself, the platter again sinks and in twenty seconds relations with the disks ordered by your neighbor. The plates, etc., give changed, in a very convenience spit from the platter with fall providing the service are due to the dispendence abstractaging in the service are due to the dispendence and relightly of the services are due to the dispendence and relightly of the service are due to the dispendence and relightly of the service are due to the dispendence and fragitation are relations. The platter and dispense and dark neight are princed at platerals of states of the sead and suggisted new restaurant tables, or short guisses, who can thus be served by a single water in addition, its "countries" varior is provided for overy

eighty gnests, for the work of changing plates, etc. Each guest receives, with his order, a check which is numbered to correspond with his individual push but-Payment may be made to a cashler at the door, or by means of the service elevator, according to the

system adopted. Tables with twelve seats, for dinner parties, will be operated in the same manner, except that each dish will move along the table to the person who has ordered it, guided by the unseen mattre d'hotel with the aid of a wide-angle periscope

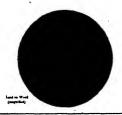

The visitor to the basement will see dishes of food ming automatically from the adjacent kitchens to the hundreds of little elevators that communicate with the

restaurant and the apartments, and solled dishes going automatically from the elevators to the electric washing

The plan adopted for the electric hotel is the result The pain adopted for the electric note is the result of long study and research on the part of its projector, M. Georgia Kusp, in collaboration with M. Danger, the well known Parisian architect. The bedrooms are conwell known Parisian architect. The bedrooms are con-structed and arranged on an ingenious system which allows the little elevators to reach the rooms without wasting space or making themselves completions. The rooms are separated by corridors two feet wide, in which the electric wires and the hot and cold water so pipes are placed. There are no radiators in the reopis, which are heated by a novel system involving no com-There are no radiators in the respits, plicated apparatus. Danger of fire is eliminated by with placing all wires and pipes in condults of fiber-cement.

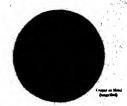

## Metal Plating With the Air Brush

The Remarkable Results Obtained With the New Schoop Process

How Pulverized Metal is Sprayed on Objects by a Novel Invention

NUMBER of processes for depositing a coati A NUMBER of processes for depositing a comment metal upon the surface of objects—usually it selves made of metal—have been well established selves made of metal—have been well established. many years past. The principal of these are the electrolytic method of plating, and the application of a coating of melted metal, as in the so-called process f "gaivanising" iron in the manufacture of timplate. But these processes have their disadvantages. Elec-

tro-plating is a somewhat delicate, and at the best a alow operation. Gaivanising, too, is not altogether a snow operation, and many hitches are liable to occur in the process. At the best it is crude, the product is sot very stable (diplate runts rather easily, as every one knuws) and delicate objects, with fine markings or re-entrant corners, can not very successfully be treated by immersion in a bath of molten metal.

We have had occasion to refer to the new proce We have had occasion to refer to the new process invented by the Sivias enqineer, Schoop, which not only is free from the disadvantagee pointed out above of the older processes, but which has a practically sufficient of the control of the practically sufficient of the control of the practical of the carried out and the fact that it can be applied to lifer-sity any surface whatever. A moitre meant better ardently be used only in dealing with metals are other productions of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process of the process of the process of the pro-ting of the process resistant materials. An article in order to be capable
of being electroplated must be conducting at least on its ecting at least on its surface. But Schoop's process will cost any surface, however perishable or fragile (paper, lace, etc.) in the briefast time with a perfect metal coating.

Reveral types of apparatus have been devised for carrying out the process, but in its most perfect form the thetrument employed is a "pisto" held in one hand, and provided with an oxyhordoren blast, which pro-gressively melts a metal wire fed to it, while an air rays the melted metal against the surface to

An idea of the applications to which the probe put may be gathered from the examples shown in several of our engravings. Objets d'art molded from etc., and coated with a film of metal, form exceedingly attractive ornaments. But probably the most important use of the process will eventually be its application in the industrial arts, for lining vessels to make then resistant to various liquids and reagents, for coating structural work, such as from bridges, to protect it from the weather, and for innumerable analogous purp The coating prepared by Schoop's process adheres tenactously to the surface upon which it is deposited. This firm grip is explained when we look at the microphotographs on this page, which show how the metal forming the outer coating forms an intimate bond with

The film boxes and internal mechanism.

Trademark made by spraying tin through a stencil on terra cetta.

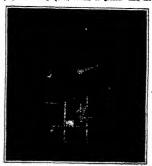

A terra cotta urn and a cement lion, both covered

the surface of the underlying material—copper in one case and wood in the other.

The Schoop process is still in its infancy, at least so far as its application in the arts and industries is

someoned, and there is every reason to expect a wide field of usefulness for it in the future. But while the couling obtained by direct spraying of an unprepared surface adheres thus tenaciously to the an unprepared surface ameres thus tennerously to use substration, it is quite a simple matter to obtain a detachable casting or mold if the surface is previously prepared with graphite, talcum or grease. And the

Front view showing the air mother and gyre

old can be made just as thin or as thick as simply regulating the length of time of apraying, is needless to point out the many possible applicati of this form of the process.

#### A Cinematograph Hand Camera By the English Correspondent of the Scientific American

DURING the past few years the increasing demand for topical and big-game, or hunting, motion pictures has emphasized the shortcoming of the coaventional apparatus for such work, and the need for some compact, tight instrument which can be handled with the simplicity and case of the ordinary snap-shot app ratus. The first commercial success in this direction exynski, the Polish scien has been achieved by Mr. Prossynski, the Polish scien-tist resident in England, who has perfected such an inent, which is known as the sero

The camera is driven by compressed air and is absolutely automatic in its operation, the exposures being made regularly at the desired number per second, all the while the control button is depressed, and so long as there is sufficient air in the reservoirs to drive the mechanism. The instrument, measuring 12 inches in mechanism. The instrument, measuring 12 inches in what he length by 84% inches in width by 64% inches deep and selength by 84% inches in width by 64% inches deep and weighing 14 pounds, is entirely self-contained. It is fitted with separate film boxes inside the camers, any number of which may be carried and changed in full daylight like the common map-shot camers, apol. When loaded, the camera normally has 800 feet of film in the spool-loop, and the air reservoir as are of wificient capacity to enable 600 feet of film—two boxes—to be expected upon a single charge.

Externally the camera resembles the ordinary and solution instrument, with the exception what on once

shotting instrument, with the exception that on one side is the film counter, while on the other is the airvalve, the speed regulator, and the starting button, to-gether with view finders. On the top is the indicator gether with view induces. On the top is the industry, notifying the volume of air remaining in the compressed air reservoir. The camera is divided into two main compartments. One contains the film boxes, access to which is provided by means of a side door, while the other contains the intermittent film-moving mechanism, motor, air cylinders and a powerful gyroscope. If ired, the whole of the internal mechanism can be withdrawn intact in a few moments for the purpose of cleaning and overhaui, and without disturbing a sin mponent part.

The compressed air is contained in four cylinders placed side by side and interconhected, so that as soon as one is exhausted the next comes into action.

air reservoirs are charged by means of an ordin (Concluded on page \$644)

## WARNER QUALITY AUTO-METER

## Why the Highest Priced Cars All Have Warners

THE Warner Auto-Meter is associated with more high-grade and high-priced cars than any other automobile accessory in the world.

As a result it is proudly and specifically mentioned, advertised and catalogued by all prominent manufacturers of high-priced automobiles.

This is a logical, natural situation because the Warner costs double the price of other speedometers. And the Warner costs double the price because of the exacting manufacturing methods by which it is built. The finest watches, laboratory and scientific instruments are given no greater care in their making.

97% of all high-priced automobiles for 1913 are equipped with Warner Auto-Meters.

#### Logal Notes

Copyrighting Meving Pictures.—Since the institution of the law last summer for 1,055,703, Jacob the protection of moint pricetures, only in a Massellies, in the neighborhood of 900 applications for formed from a sit copyright registration for the subjects paper. In making manad have been filed. Under the law formed deem as mansed have been filed. Use the application for registresism must be accompanied by the title and description, together with one print taken from each scene or act of a motion picture photo control at title and description ot less than two prints take ure other than a photo play.

Continuing Applications in the Court of Appeals.—In the case of Field v. Colman, the Court of Appeals of the District of Columbia in its decision refers to the question of continuing applications. The right of an applicant by multitude appli-cation, to relate back to the date of filing cation, to relate back to the date of filing the first application for reduction to practice, is held to depend breadly upon whether the substituted application is for the same invention as that disclosed in the original application; not that practical disclosure of the first and acceptance of the content specific disclosure of the first and second applications may be different, or even patentably different, if generically they relate to the same invention.

Some Adjudicated Patents.—In National come auguneated Fatents.—In National Casket Company v. Stolts, the reissue patent No. 12,750 (original number 619,-567), issued to the National Casket Company for a gause face plate for burial caskets has been held devoid of invention and invalid. The Hildreth patent, No. and invalid. The Hildreth patent, No. 823,284, for a cendy-pulling machine, has been held void as to claim 4, as broader than the invention in Hildreth V. Laure & Suter Company. The Fishel design patent, No. 37,005, for a design for clasp pin has been held not infringed in Fishel, Nosler Company V. Fishel & Co. and the Fishel patent, No. 384,979, for a jewel bur has been held infringed in Fishel, Nosler Company V. Fishel & Co. Month of the Fishel patent, No. 384,979, for a jewel bur has been held infringed in Fishel, Nosler Company V. Fishel & Co.

Adjudication of Hot Water Heate Patents.—In Rund Manufacturing Com Patenta.—In Rund Manutacouring Com-pany v. Pittsburgh Water Heater Company (U. S. C. C. A.) the Rund patent, No. 761,409, for a gas burner has been held valid and infringed and in Rund Manufacturing Company v. Pittsburgh Water riester Company the Rund patent, No. 903,007, for a water bester has been held valid; also intringed as to claims 3, 5 and 6, and not infringed as to claim 10.

Assignee's Right to Prosecute Applica-tion.—Commissioner Moore in az parte Kyle has held that a petition by an assigned of a part interest to intervene in the pro-secution of an application will be dismissed where not accompanied by proof of service upon the other assignees and upon the

A Design Declaion.—In the case of az paris Fulda, Mr. Commissioner Moore hald that where a design is for the form or configuration or involves the relative per-portions of paris of an article of manu-facture, such article must necessarily be disclosed in the application, but where the design is for an ornament adapted to be applied to any article of manufacture it is not necessary that applicant disdoms the applied to any armote of manufacture it is not necessary that applicant disclose the design as applied to some particular article of manufacture. In the decision the Comor manuracture. In the decision the Com-missioner says while it is possible that applicant might obtain protection for his design under the copyright act, it is believed he is clearly entitled to the protection

afforded by a design patent.

Extensiveness of Use in Engineering 1997, which related to the species and of or future for the control of the

Fereign Artificial Marble .- Consul William J. Pike of Reichenberg, Austria, re-ports that considerable interest is taken in an invention by a citizen of Reichenin an invention by a citizen of Reichen-berg, Bohemia, of a process of producing marble substitutes in imitation of the highly prized Italian, Egyptian and Sels-burg marbles. It is claimed that the pro-duct is strong and is not liable to crack. The artificial marble is made partly by hand and partly by machine, while the cutting and polithing is done by machinery. The process is said to be in operation in Yeans, Berlin, Manshelm and Handwen a, Berlin, Mannheim and Hambi

at is a well-known fact that vermin are attracted by light. A Canada It is a well attracted by light. A Canadian inventor Mr. G. A. H. Muller, has patented as Mr. G. A. H. Muller, has patented an insecticide in which that principle is preactically applied. He has invented a luminous aticky compound or paint, which does the work of the ordinary sticky flypaper in daytime, absorbs the rays of light at the same time, and becomes luminous as night to finish its work of extermination. A Nickel-in-the-Slot Typewriter.

A Nickel-la-the-Sict Typewriter.—Harry Bates of Albaya, N. Y., assigner to Underwood Automatic Typewriter Pay Station Company, of New Forc city, has passented, No. 1,003,048, an apparatus in which a coin controlled typewriting machine is normally out of condition for use and, by the deposit of a wittable coin, can be put into condition for use for a period limited by soloriesty, at the termination of which by clockwork, at the termination of which period the machine is automatically looks or returned to normal condition in which it cannot be operated. Such machines can be seen in many hotels.

and be seen in many surveus.

Aid to the Study of Musical Compositions.—In a patent, No. 1,088,569, Percy
F. Cowing of New York city provides a
means for the study, of musical composimeans for the study of musical compositions which includes a record for automatic mechanical instruments. This record is divided into socious or metric, means being provided with matter descriptive of the sections and means being also provided with means being also provided with means and means being also provided subjects to the sections and means being also provided subjects to the sections.

## Why Repair Shops Keep Busy

No wonder automobile repair shops have so much to do, for— The automobile is the most severely used piece of machinry in all the world.

- -It suffers the most and worst shocks and strains.
- -It receives the least expert care in operation.

Because of this, the automobile ought to be the most carefully usigned and the most carefully built machine in all the world.

But it is not, in most cases.

#### Here Are the Plain Facts

Four-fifths of the makes of cars on the market today are neither designed nor manufactured by their so-called makers. They are not even designed as complete, unified cars, but are collections of many groups of finished stock parts—bought here and there, wherever they can be secured most readily and cheaply.

It is nearly a miracle if these parts happen, in any instance, to form a balanced, harmonious, durable, complete car—for these parts, remember, are designed and finished, not for some one particular car, but—

- -as separate, unrelated units,
- -by separate, unrelated groups of men,
- -in different factories,
- -at different times
- —these designers having no knowledge of what other parts are to be used in any particular car assemblage.

#### 80 per cent.-Think of It

Eighty per cent. of American automobile "makers" are gatherers and assemblers of finished parts, made under these conditions. That is the cheapest method of "manufacture." Futhermore, it is a method not practiced and not countenanced in any other branch of the machinery-producing industries.

Locomotives, stationary steam engines, electric motors, machine shop equipment, printing presses—machinery that men buy with careful judgment and at big prices—are manufactured (not assembled) products. They we got to be designed and manufactured as ONE UNIT in order to have precise balance, and uniform strength and endurance, to withstand severe use, to be right. A railroad would refuse an assembled locomotive as it would refuse lead rails.

#### Only One Safe Method

Machinery manufacture is an old, stable, and experienced industry. And the machinery industry says that the only safe way to build an enduring product is to have that product designed and man-

## **WINTON SIX**

Long stroke motor, left drive, center control, electric lights, self-starter, finest mohair top, easily handled curtains, rain-vision glass front, best Warner speedometer, Waltham eight-day clock, Klaxon electric horn, rear tire carriers, four-cylinder tire pump, demountable rims, full set of tools, German ailver radiator, metal parts nickel finished. Fully equipped, \$3250

ufactured under the roofs of a single plant, and to have the whole work supervised by some one richly qualified and able man.

The principle is as old as the hills. Three hundred years ago, Descartes, first of modern philosophers, wrote: "There is seldom so much perfection in works composed of many separate parts, upon which many different hands have been employed, as in those completed by a single master."

#### Here's A ONE-UNIT Car

The Winton Six stands out as a distinctively and enduringly excellent automobile because it is produced on the same plan that the greatest and ablest of machinery makers adhere to so zealously.

It is designed and manufactured in one comprehensive plant. That plant has but one product—the Winton Six car, made in one single model.

Every part of the car is designed and manufactured to harmonize and co-ordinate with every related part.

From start to finish, the production of Winton Six cars is personally supervised by one man, Alexander Winton, founder of the gasoline motor car industry in America, and the world's most experienced six-cylinder specialist.

#### What's the Result?

That's why the Winton Six, alone, was able to change highgrade demand from four-cylinder cars to Sixes. That's why the Winton Six withstands the hardest of service and holds the world's lowest verying reports record 22 cents are 1000 miles.

world's lowest repair expense record—29.2 cents per 1000 miles.

That's why the Winton Six is the finest possible specimen of ONE - UNIT Construction, which means that it is precisely the kind of car that fully satisfies the most exacting purchasers.

Let us send you a catalog.

MAKERS OF
Standard Full Weight Steam, Water, Gas and Line Pipe, Black and Galvanized

The Most Spilonal Source of Poirs

(Concluded from poor 27th.)
The value of the whole group of the ventions lies in these can heat absorbers, which generate the steam required to run the engine from the sun's rays. These heat absorbers and ste

These heat absorbers and steam generators are, in this particular plant, site is number. They are each 200 feet long sind 13 feet wide at the top. They consist of parabolic frames of very light structural from set with mirrors in such a manner that these mirrors catch the sun's light and redect it all on the two sides of the and reforc it all on the two sides of the long folders superanded in that portion of the frame where the sun's light courserges. Every five agare feet of sunlight received by the mirrors are focused thereby upon one square foot of the bolices, thus quin-tupling the light power. However, as the steam pressure is not allowed to go over atmospheric pressure (equal to 212 deg. Fahr.) the temperature of the hollers never goes above 212 deg. Fahr. and the excess heat is transmitted into the water and produces great volumes of low-pres

The hotlers are flat bottomed, and along the top of each runs a 8½-inch diameter steam pipe, which gathers the steam along ole line and carries it from each of the hotlers into the main steam pipe through which it goes to the engine.

The boilers are constructed of cast iron

in the present plant, but in future plants will be stamped quickly and che pleces 12 feet long from steel tubes one

The steam after passing through the engine and doing its work is condensed into water and pumped again into the bollers. Thus the same water is used over and over again, and only the very little needed to compensate for accidental leak ago is auted. As practically no new water is used there is no danger from the boil-ers becoming clogged with mud or scale. High-pressure steam up to 300 pounds

per square inch can be generated by thes limit absorbers, but this is not done, mair ly because at the high temperature of this stram too much heat would be lost by conduction and convection into the surrounding air, and secondly, because, were high-pressure steam used, the boilers would have to be very strongly construct-ed, and cost considerably more money, and necessitate heavier frame construction to carry them than is now the case.

The five heat absorbers carrying the beliers are set in line due north and souti on rollers and gears carried on proper foundation posts of concrete, and are turned slowly from an eastern aspect in the morning to a western aspect in the evening, so that at all times of the day they exactly face the sun, and generate

The very important element of expan sion and contraction was carefully considered in the construction of the heat ab rs, and many trials were made be fore all the disturbances were eliminated.

The boilers are covered with a single thickness of window glass to prevent loss

Sun power can be generated in large lants located in the desert on the border of arable land, and the power transmitted by electricity over large areas.

The construction of the Egyptian sur ower plant is par ularly simple, and power pant is particularly simple, incomply, practical in every way. Any common sugment can run it. Dwing to the heet they ordinary materials are used in its construction, cannot say a sent and and everything is spore greated and

#### The Ten Greatest Inventions

(Concluded from page 1991) resulted in a protest from a number of readers who misunderstood east object in readers who misunderstood eiss' object in publishing the list, and easied as 'eo se-count for including in it mean; insentense that did not full within, the 'spice, at the contest. However, the majority of our readers without minimum we did not indores all of the inventions in the list, and the result of their rote is very

## Are you getting the maximum amount of daylight in your plant?

Or is a large percentage absorbed, swallowed up, wasted, in your ceilings and walls? The difference can be reduced to dollars and cents, in your lighting bills, the efficiency of your employees, the quality of your product.

You can get the full value of every ray of light that comes in your windows and increase your present light 19 to 36 per cent by painting your ceilings and walls with Rice's Mill White Paint.

Rice's Mill White is an oil paint giving a glossy, tilelike finish without the use of varnish. It will not crack or craze under the jar of machinery, and remains white longer than any other gloss paint.

Rice's was the pioneer "Mill White" paint. It made the reputation of the name "Mill White." The special process by which it is made cannot be used by any other paint manufacturer.

## Rice's Granolith

KIGC & LITAMOISTA
A tough and elastic permanent
finish for concrete walls. Becomes a part of the cemen towhich it is applied. One coat
sufficient, unless a gloss is desired. Makes the best possible
primer on inside concrete and
brick for a second coat of Rice's
Mill White Paint, giving a tiletiles, enamed finish at no more

Rice's Mill White is sold direct, in barrels containing sufficient paint to cover 20,000 square feet, one coat. If you have that area of ceiling and wall space to cover, Write for Booklet and Sample Board

WE HAVE PROOF-ELECTRENE CO.

#### During a Period of Nineteen Months This "Electric" Was Out of Service Only Two Working Days

—and that two days loss was due to other causes than the battery. This battery was an "fronciab-Exide" it was placed er, 1911, and up to April, 1913, had given —an average of about 35 miles per day. is just such continuous, unfailing service as this that makes an ectric vehicle—whether pleasure or commercial—a real delight its owner. And it is just this service that is supplied by

THE ELECTRIC STORAGE BATTERY CO.

## ee Puncture Proof Tires

It is easy to call a tire "an extra service tire." And sometimes hard to find the extra service. But with Lee Puncture-Proof Pneumatics you get

#### a cash refund

of every penny you pay for puncture-proof insurance in case the tire fails to make good the name. Isn't that buying real extra service, on a sure-proof basis? There isn't a single way you can lose.

If you do puncture the tire (we guarantee you will not)—then your wonderful-ly efficient extra-mileage tire costs you not a cent more than an ordinary

Are you still skeptical? Write "I doubt it" on a postal, mail to us and we will send Booklet No 6, with convincing proofs and service records. For Sale in All Leading Cities

LEE TIRE & RUBBER CO.

CONSHOHOCKEN, PA.

## The Chronology of Aviation

THE Scientific American has received from Mr. Hudson Maxim and Mr. William J. Hammer, a limited number of the reprints which they have just issued of the very complete "Chronology of Avaston," originally prepared by these gentlemen for the World Almana of 1911. The data enabrace the essential facts relating to serial progress. In addition to a short historical relation, one finds herein tables giving altitude records, speed records, quick starting and slow-speed records, passenger carrying. English Channel and other over-water flights, cross-country flights, notable distance and duration flights, etc. There are also statistics relating to accidents and data relative to pherical and drigible balloons or airrhaps, etc. Of no small interest are the tables giving the most important flights of the Wright brothers. There are doubtless many readers of the Scientific American who are much interested in this subject and who would be glad to secure a copy of this interested in this subject and who would be glad to secure a copy of this interested in this subject and who would be glad to secure a copy of this interested in this subject and who would be glad to secure a copy of this interested in the Scientific American who are much interested in the subject and who would be glad to secure a copy of this interested in the Scientific American who according to the Scientific American who are much interested in the Scientific American who according to the Scientific American who according to the Scientific American who are much interested in the Scientific American who according to t SCIENTIFIC AMERICAN, 361 BROADWAY, NEW YORK

There was a straggling vote for the other subjects in the list. Burbank's work received 23 votes, l'asteur's work 20 votes Acetylene Gas from Carbide, 17; Mercury Acetylene Gas from Carlide, 17; Mercury, Vapor, Lamp, 7; and the Preservation of Sugar Producing Plants, 7. In addition to this there were about 60 inventions mentioned which did not appear in our list. The more important of these were the Combined Motion Picture and Taiking Reads and Carling Motion Picture and Taiking Reads and Carling Motion Picture and Taiking Reads and Picture and Taiking Reads and Picture Machine, 10 votes: Edison's Storage Battery, 6 votes; Autometic Player Plano 4 votes; Pulmotor, 4 votes; and Tele phone, 4 votes; while the rest were nearly all represented by a single vote each.

Evidently there is not much disagree-ment about the first five inventions in the list, but after that there is a sudden drop m 63 per cent to 87. It is interesting to compare this vote with the list in the first prize casay. Mr. Wyman's selec-tion of Wireless Telegraphy is indorsed by 97 per cent vote, his Aeroplane by 75 per cent vote, the Automobile by 66 per cent vote, Motion Pictures by 63 per cent vote, the Turbine by 34 per cent vote, Elec tric Furnace by 21 per cent vote, the Composing Muchine by only 15 per ce while the Cyanide Process, the Induction white the Cyanada Process, the Induction Motor, and Electric Welding received scarcely any attention from the readers at large. On the other hand, the X-Ray Machine which polled such a high vote with the renders was entirely ignored by

After all is he not right in rejecting the machine but a Crookes tube and a Ruhm korff coil, both old inventions? Is it no the discovery of the rays rather than the machine that is of an epochai character? But discoveries not patentable are ex-pressly excluded from the contest. What about radium then? Surely the process of producing radium involves invention. of producing radium involves investions. Why is it not patentiable? Why, is not radium chloride patentiable just as are other chemical compounds? Even such subjects as the aeropiane and attemptible are open to question. The judges had to consider the question of whether this internal combination makes with the learned combination makes and the learned combination and the learne ternal combustion motor was not really iternal combustion motor was not really the plones inyention to, which credit should be given for the automobile, and acropiane merely a lite with a motor in it and is not the automobile an ordinary car-riage cutpode with mechanical power? The whole subject is one full of genetics. and consequently of exceedingly gre

## DON'T BE WITHOUT IT

#### The Heavens in November

(Concluded from eage \$41.)
The last two lines, having been deriv by extrapolation, may be in error by s

half way between a Cygni and the north-ern stars of Delphinus on November 1st about 3 degrees west of a Cygni on the 17th, and about midway between s and of Cygni on the 25th. It will therefore bevery easy to find. Metcalf's comet has been passing southward through the sam region of the sky, and, on the evening of October 22nd, the two comets, according to the ephemerides, came within 40 min-utes of one another—in the same low-power telescopic field—an occurrence so unusual ately the predictions were not published in time to enable advance notice be given in this column.

The Heavens

finding Westphal's comet may be found on our map, well down in the west and northwest, though early in the evenings they will be much higher up. Below Cygnus is Lyra, and Ursa Major and Draco are also low along the northern horizon, while Casslopela swings high above the pole. The splendid winter constellatious have come full into view in the cast and south east-Auriga, Gemini and Taurus, Orlon and the Great and Little Dogs. Perseus Andromeda and Pegasus form a line siretching westward through the zenith while Cetus, Eridanus and Aquarius or cupy the great dull region in the south

#### The Planets.

Mercury is evening star until the 23rd, when he passes through inferior conjunc-tion and becomes a morning star. At the beginning of the month he can just be n in the twilight, setting at 5 50 P. M the dawn, rising at 5:40 A. M.

Venus is a morning star, rising about 6
A. M., and still fairly conspicuous. Maris in Gemini, south of Castor and Polluv orning star, rising about 5 of rises about 9:20 P. M. on the 1st, and 7:40 on the 80th. He nearly doubles in es during the month, and exceeds all the stars except Sirius.

Jupiter is evening star in Sagittarius dropping fast into the twilight. He sets dropping fast into the twilight. He sets at 8:45 at the beginning, and at 7:20 at

Saturn is in Taurns, just approaching NATURE 18 IN TARIUS, JUST approaching opposition, and rises at 6 P. M. in the middle of the month. He appears fully as bright as Capella, and but little fainter than Mars. Uranus is evening star in Capricornus, too low in the west to be il seen. Neptune is right oppos the heavens, on the borders of Gemini and Cancer, and can be observed in the m ing hours.

The Moon

First quarter occurs at 1:34 P. M. on the 5th, full Moon at 6 P. M. on the 13th last quarter at 2:57 A M. on the 21st, and new Moon at 8:41 P. M. on the 27th. The Moon is nearest us on the 9th, and farth est off on the 25th. She is in conjunc tion with Jupiter on the 3rd, Uranus or the 4th, Saturn on the 15th, Mars and Mercury on the 27th, and Jupiter again on the 30th—none of the apparent aproaches being at all close. Princeton University Observatory.

sever. 600 jounds, as emple margin of mater is provided. Chinging the cytin-dent is an attendately simple straightfor-ward process. the only precention neces-sary being a passe of about 50 seconds when each 500 pounds pressure is attained so as to permit the pump and connection to second warm. The flux boxes are mounted side by side, the unexposed box being pieced in the inseriment position. The film is threaded through the intermittent mechanism in the

through the intermittent mechanism in the itinial manner and returned into the ex-posed film box mounted beside the first box, and upon the eams spindie. The groupops, though small, is of great power, and by its means all small vibrations, such as that produced by the running of the mechanism, the speedy movement of a vahiefe, and so forth, are completely ab-

In operation the camera is held up or the cheet so that the view finder is brought level with the eye, like a rife sight, and in this way one is able to follow the acone, keeping the main features in the center of the picture, with the utmost case. Both hands are free to hold the instrument during exposures, as it is not sary to keep the finger upon the but-When all is ready for exposure the ton. When all is ready for exposure the air valve is opened by turning a small knob. This permits the compressed air to pass to the motor. The latter is unable to salf-starting and the air is unable to eccape. Then, sighting the camera, the starting button is depressed and given a starting button is depressed and given a starting nation is depressed and given a sharp turn. This sets the motor in mo-tion, and it will continue running until a slight pressure is imparted to the button once more, when the mechanism stops im-mediately. Thus one has complete control over the camera, and in photographing topical subjects no waste of film need be incurred. While it is not necessary to close the air valve upon completing each exposure, this precaution should be observed when work is completed, or when the film box requires changing. Although the normal speed of exposure is streem pletures per second, this speed may be varied even while the camera is being used, and the eye is sighting through the view finder, merely by moving the speed

The governing system is very positive and insures that the same ratio of expos-ures and speed of the gyroscope is main-tained when the reservoirs are nearly exhausted as when fully charged.

This camera has been embraced by several well-known cinematographers such as Cherry Kearton, Paul Rainey, and others, who make a special study of making mo-tion pictures of big game in the jungle, where the conditions render the use of the orthodox cumbersome instrument extreme-ly dangerous. It has also been adopted ly dangerous. It has also been adopted for photographing from seroplanes, for which work, where the conditions are cranged, it is well adapted. It is also extremely useful for work in crowded throughfares. In this case a street pro-cession or other incident may be taken without the conventors sensitive and a without the operator's securing an ele-vated position to clear the heads of the people. He merely holds the aeroscope people. He merely house the aeroscope above his head with his two hands, and by means of a special view finder placed on the under side of the camera, he can fol-low the incidents and make the exposlow the increases and make the expon-ures. It is also applicable to studio work in confunction with the ordinary tripod, the mechanical autematic control and drive being very useful at times.

Mante. Four Bidriot mone channels. Four streets appropriate the first blauvice Farming, blauping them, all logisd to the said again, smalle as square hundred to the blue forten together with four Nauport monoplates. Buth unit was aged by a pilot and an 'obe

"The results were eminently as tory, nor was the work interrupt the persistent rains, heavy clouds, and string winds. On one occasion two Bistis monoplanes were sent to reconneitre and returned after two and a half b bringing back photographs and precise in formation which enabled the commander of the red army to determine the numbers of the red army to determine the numbers, formation, positions, and movements of the entire Vercetiff—histo-division then Warrching on Milan From Pieconia and Pavis. One of the machines had flown SO kitometers (1745 miles) per hour. This speed represents, in the opision of the officers of the biplane section, an almost excessive limit for accurate observation. Those gentlemen, in fact, hold that the biplane, traveling at 100 kitogrammes (62 miles) per hour, is the ideal machine for military work, since it has the advantage of maxiwork, since it has the advantage of maximum stability and offers greater facilities to the pilot for seeing immediately beneath

"The airship performances seem to have been what many expected. Their demerits appear to have been brought out on more than one occasion, when the heavier craft was seriously mensits more active rivals.

"In more active rivals.
"In view of the fact that knowledge of
the various types of aeroplanes is not as
yet-generally diffused, and in order to prevent confusion between friend and foe, the military authorities adopted the almple plan of distributing leaslets with rough in dications of the salient points and outline sketches of the different aeroplanes taking part in the maneuvers. The Maurice Farman biplanes which served with the 'red forces were marked to distinguish them from those of the opposing side, with a large black circle and another in white

#### The South American Meat Industry

THE stock-raising and meat industries of South America are well developed and have large possibilities for future extension, according to Dr. A. D. Mel-vin, chief of the Bureau of Animal Industry, who has returned from a tour of in-vestigation made by direction of the Secretary of Agriculture.
While statistics show that Argentina is

already slaughtering up to the limit of its present stock of cuttle, Dr. Melvin was impressed with the great resources that country for cattle raising and be-lieves that it will be possible for the stock raisers to bring about a large increase in the meat output if present prices are maintained.

The cattle slaughtered for export in A gentina, Dr. Melvin says, are fed no grain whatever, but are raised and fattened entrely on aifalfa pastures. For the most part the cattle are high-grade stock, the predominating breed being the Durham with the Hereford ranking second and the Polled Angus third in number. The airalia pastures are capable of supporting many more cattle than are the native "camps" or unbroken country. In a general way the cattle raisers estimate on 21/4 acres of pasture per head for growing 2½ acres or pasture per near for growing cattle, and 3 to 8½ acres for fattening cattle. These pastures support the cat-tle the year round without any further feeding except in occasional times of drouth or invasion of locusts.

drouth or invasion of locusts.

"At the time of my visit," mays Dr. Melvin, "cattle that dressed 850 pounds were
odd for \$74.00 gold. This grade of Argontine beef, which is of very kind qualities
a pound wholesale. Besides the price recattle for the control of the control of the conpart of the control of the con ceived for the ment there is a est ceived for the ment there is a considerable return from the hide and the affat, and since the entrance of Ambreion mackets into the South American trade these hy-products are being carefully propagated and

## The Electrically-driven Vessel "Tynemount" By Frederick C. Coleman

THE first ocean-going vessel directly driven by electricity has just been completed at Wallsend-on-Tyne, England, and is about ready to cross the Atlantic Ocean for service on the Great Lakes. The operation

en the reasel will be watched with great interest, for although the same type of propulsion was used on the small "Bleetric Are," the latter is not to be compared with the "Tynemount," which has a length of 250 feet, beam 42 feet 6 inches, moided depth 19 feet, and a cargo capacity of 2,400 tons.

The propelling machinery of he "Tynemount" is accommodated in a compact engine-room under the poop of the vess l, and occupies only about one sixth of the ship's length. On opposite sides of this room are two six-cylinder Diesel engines, each capable of developing 300 brake horse-power at 400 revolutions per minute. Direct connected to engine is a 8-phase gener ator furnishing electric power to an induction motor mounted directly on the propeller shaft. The rectly on the propener shalt. The siternators when running at their normal speed of 400 revolu-tions per minute each give an output of 500 volts and 270 amperes per phase, which absorbe the full power of the en exciter is direct coupled to each alternator and is capable of giving an exciting current of 30 am-

market Marine

peres for normal working, which can be increased up to 50 amperes while maneuvering.

In ordinary practice where two alternating-current generators are connected in parallel it is necessary that they be run up to speed, and be synchronized before being switched on to the load. But such an operation would be imparcitable in ship work. Accordingly, a very ingenious arrangement has been adopted. The two generators are provided with six and eight poies, respectively, giving a frequency of 20 and 20.6 cycles per second, respectively. The rotor of the motors is of the well-known squirrel cage type, but the stator is provided with two entirely separate windings, one of thirty and the other of forty poles. When these two wind-

ings are supplied with current at 20 and 20.6 cycles, respectively, they give the same synchronous speed of 80 revolutions per minute. The motor then absorbe the full power of both engines, and drives the propeller to which it is directly coupled at a speed of 78 revolutions per minute. To obtain a lower speed, the conscitions are altered so that the 20-cycle generator supposting the contractions are altered so that the 20-cycle generator sup-

View of the engine-room, showing one of the generating sets.

piles the 40-pole winding of the motor, while the 20.5 creis atternator is shut down, thus throwing the 30-pole winding of the motor out of errice the superior winding of the motor out of errice the year of the superior of the superior winding the superior wind

never run in parallel, so that it is immecessary to synchronize them. The motors are readily reversed by interchanging the connection of the two phases

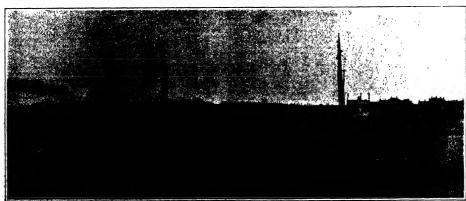

The switch genr consists of a controller having five different positions, full speed ahead, half speed ahead, stop, half astern, and full ustern, while a second switch is employed for the purpose of introducing resistance

into the shaint circuit of the exciter. The continers of both switches work under oil, but it is madylsable that the continets on the main switch should be required to break the large main current flowing to the motor. The two switches are therefore interlocked, so that it is laugustable to work the main switch except when all the resistance has been furtheduced but the except when all the resistance has been furtheduced but the exciter field cell. There is then whole system is dead. With the resistance in the calcute teller cut, the main switch can be moved to any one of its of the and working positions, and when the main connection has been audit on the main connection has been main connection the short switch level is pulled over, so as to cut off resistance and restores occupation.

and restore excitation.
It will be seen that the whole handling of the ship can be enried out by means of two levers which are so hierbicked as to be practically footpreaf. In the present instance these switches are in the engine room, but it is evident that by lengthening the connecting eniles they could be placed on the navigating bridge,

The number of electrical instruments provided has been kept down to a minimum. There is only one animeter and one voltmeter for each atternation and an ammeter and voltmeter for each excite. The landfling of the switch goar is so simple that there is no neces-

sity for multiplication of measuring instruments. The electrical drive allows of a reduction in the machinery space and also in the bunker space required, thus increasing the eargo empachy of the vessel. As a subsidiary advantage, it leads itself results to distant control, and in may case where II may be found advashibe the switchigen can be put out the bridge, thus placing the cantrol of the motor driving the propelle into the lands of the nativating officer.

The "Typespecial," a freighter for the Great Labor, driven by electricity generated by two Dicael-augme-alternator ects.

Here the oak funder along the sides for protestion in the locks.

#### SCIENTIFIC AMERICAN

NEW YORK, SATURDAY, NOVEMBER 8, 1913 ed by Munn & Co. Incorporated. Charles Allen Munn Frederick Converse Beach, secretary and Transurer all at 81 Broadway, New York

fromes and Gardens sined subscription rates and rates to foreign con-cluding Canada, will be furnished upon application.

Munn & Co., Inc., 361 Broadway, New York

The Editor is always giad to receive for examination illustrated articles on subjects of timely interest. If the piotographs are surely, the articles short, and the facts nutleutic, the contributions will receive epecial attention. Accepted articles will be paid for at require space rates

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

#### Scientific American's Contribution to the

Development of the Racing Aeroplane T the time of the acropinue meet which was A held on Long Island in the autumn of 1910, the Editor of the SCIENTIFIC AMERICAN undertook to forecast the line of development which would be followed in the designing of future racing aero-planes. In an article published in our issue of October 22ud, 1910, we wrote: "A study of the trend of de opment in aeroniane construction renders it possible predict, with some degree of certainty, the leading characteristics of the aeroplane of the future, and especially of that type which will be built purely for racin purposes." Our design was based upon a recognitio of the fundamental principles: that the chief resist-ances encountered by an aeroplane are those due to the lift and the head surface, or total projected vertical a, and that while the resistance due to the former is fairly constant, the head resistance increases approximately as the square of the speed, and that hence it is necessary in a racing machine to reduce the head resistance to the least possible limit consistent with structural requirements

We puinted out that this consideration of head resistance ruled out the hiplane because of its mass of struts and wires, and rendered it necessary to design the monoplane strictly in accordance with the stream-line theory of resistance, that it necessitated the abolitime theory of restance. That it increasingted the about tion from the monoplane of external sirnis and guy-wires; the adoption of a body of torpedo form; and the countraction of planes of sufficient thickness to admit of building entirely within their external surfaces internal girders or frames having sufficient trans verse strength to prevent buckling and hold the wings up to their work. It was suggested, moreover, that the body and wings, as thus modeled, should be built of some high grade steel alloy, such for instance as vanadiam steel—a construction which the rapid development of the tensile and other desirable qualities of alloys promised to render possible in the ear future Furthermore, it was predicted that such chine, provided with a Guome motor of from 75 to 150 horse-power, according to the size of the un-chine, would be capable of making speeds of from 100 to 125 miles an hour

So much for prediction The event has proved that, in the technical world at least, prophecy based upon a recognition of fundamental scientific laws cunnot go a recognition of tundamental scientific flows cubinol go very far wide of the mark. This is shown by a study of the whining machines in the three contests for the Gordon Bennett Cup which have taken place since this orticle was published

The Nieuport monoplune, with which Weymann cap-tured the cup for America in the 1911 meet held in England, was built in accordance with the streamline theory, the long, tapered fuselage being entirely covered in with fabric With a motor of 100 horse-power, this muchine easily surpassed its competitors, averaging 78 i miles per hour, as against 75.9 miles per hour made by riot of equal power.

In the meet of 1912, the winning machine, a Deper dustin monophine, which covered the course at a speed of 106 miles per hour, showed a still closer approximation to the Scientific American type. The body, of torpedo form, was sheathed in with a smooth coat of thin, laminated wood, and although the struts and gur where were still present to be acceptable. wires were still present in the machine, they had been cut down to offer as small a head resistance as then was thought practicable.

In the race for the cup held in France on September 20th, 1913, it is significant that a speed of 125 miles

an hour, predicted by us in 1910, was achieved by a machine which bears a remarkable like pictured by us at that time. Not only is it of true pictured by us at that time. Not only is it of true torpado form, but the construction of the wings and the running gear shows evidence of a further effort to re-duce head resistance and eddy making. The struts for the overhead guy wires are very low; the whoela are sheathed; and the frames in which they are car-ried are formed with a cross-section calculated to no. ried are formed with a cross-section calculated to pre-

ried are formed with a cross-section calculated to pre-sent as small wind resistance as possible.

In one respect our prediction as to the form of the future aeroplane has proved to be wrong. Basing our expectation upon Langley's experiments, we believed that the wings of the future racer, like those of the that the wings of the turns racer, has those of the albatross, would be long and narrow. Experience has proved that better results are obtained with a wing that is relatively short and broad—and this, by the way, is strictly in favor of the construction of wings ree from guy wires, in which the proper transverse strength is afforded by girders placed entirely within the wings. The bending stresses in wings of a given shape increase proportionately to the length of the wing; and if the wing area were so distributed that the wing had a greater width at the body than at the tip, it will be possible to secure sufficient girder depth tip, it will be possible to secure sufficient girder depth for strength, and still retain the flat curve which has been found to give the best results at speeds of 100 es an hour and over.

Prevost's winning machine differs from that sug gested by the Scientific American, furthermore, in the fact that we provided a pneumatic cylinder and con-nections, by means of which the running gear could be folded back against the body of the aeroplane as soon as it took the air. We are still of the opinion that such a construction is practicable. If it were adopted, the total head-on resistance would be very greatly de-

It is of interest to note, in passing, that we for the Scientific American machine of 1910 the use of a pneumatic cylinder, placed transversely to the ho of a paeumatic cylinder, placed transversely to the body, for operating the wing thys, the valve of the cylinder to be controlled by a small gyroscope. This device is uow being used on our army aeroplanes, and is being extensively tried out on many European machines. In the year 1911, an Antoinette machine entered the

ary contest in France, and this aeropiane was enlirely self-contulued; that is to say, the struts and guy wires were abolished and the running gear was low and housed practically within the body. Unfortunately this numerine was altogether too large for its power, and the great length of the wings necessitated their being nearly two feet thick at their junction with the body. Had Antoinelte machine been built smaller and of metal, and provided with a Guome engine of greater power, lieve it would have swept the field.

At the close of the recent contest for the Gordon Bennett Cup, it was predicted in some of the French impers that no further contests would be held; but we caused believe that America will permit the famous trophy to remain unchalleuged in the hands of the French people. Prevost's 125 miles an hour can be beaten, and can be beaten by a machine huilt in this country. If the gry wires, etc., of Percon's machine must be bedy somewhat lengthened, and "fined out," and the rouning gear made foldable against or entirely within the body, it is our belief that its 160 horse-power Guome engine would take it around the same course at a st approaching 150 miles per hour.

#### Completion of a Great Engineering Work

HE completion of the Los Angeles aqueduct, as described elsewhere in this issue, marks the successful ending of an arduous struggle with na ture in its most rugged aspects of mountain and desert and with powerful and subtle private interests for the possession of a priceless supply of water. The ten aqueducts of ancient Rome were marvels of engineer-ing skill and durability; but their construction stretched one can mus curamity; but their construction stretched over a period of five centuries, against the eight years that have elapsed sluce the Los Angeles aqueduct was first proposed, and the length and dimensions of the ancient Roman aqueducts bear no comparison with that of modern Los Angeles. The longest of the Roman aqueducts was 62 miles, while the Los Angeles aqueduct is 254 miles in length, from the intake on Ov is 254 miles in length, from the intake on Owens silver to the city limite of Los Angeles. The firfgation adju-ducts of the Inca Indians of ancient Peru, one of which was 360 miles long, are among the wonders of the world, especially so when it is considered that they were constructed by a people uninformed as to modern engineering science and its methods, but these prob ably exhausted centuries of time. The 850 miles of iron pipe line, 30 inches in diameter, which conveys water across the arid plains of western Australia to the gold mining districts of Kalgoorlie and Coolgardia is one of the triumphs of modern constructive hydraulic engineering; but this construction, although in a bot and waterless country, was comparatively level, while the Los Angeles aqueduct bores through miles of mosa-

tains of solid rock, cross es valleys on pillars crete in some places, and through hope steel sig

notable Australian structure.

The great Ashokan aggeduct to supply the city of New York, now in course of construction, is the only modern hydraulic entesprise insended mainly for denseste and industrial true, that compares fairly with the Los Angeles aqueduct. The New York aqueduct crosses the Hudson over a thousand feet beneath the river bed, and it will furnish the metropolis with 500,000,000 gallons daily at a cost, including its various reservoirs, of about The Los Angeles aqueduct has not much more than half the canacity, it is true; but it is about more than hair the especity, it is true; but it is about twice as long, passes through an incomparably rougher country, and its cost, when completed, will be less than one fifth that of the great New York enterprise.

#### Safety at Sea

THE Committee on Aids and Perlis to Navigation formed by Secretary of Commerce Reddeld to prepare recommendations for the use of the American delegation to the London International Conference on Safety at Sea to be held in November, recommeans that all occan-going stemmer, securing means that all occan-going stemmers, equipped with electricity, shall carry a searchlight so placed as to illumine all polars of the horison as far as practicable, and of sufficient power to distinguish a ship's 24-foot boat at a distance of not less than one nautical mile boat at a distance of not less than one nautical mile on a clear dark uight; and that all light vessels on im-portant outside stations shall be equipped with sub-marine bells, and all ocean-going vessels shall be pro-vided with means for detecting submarine-bell signals. committee recommends, furthermore, that the Inter-nal Rules of the Road be modified so that carrying of range lights shall be obligatory instead of op-tional, as at present, and that all vessels shall also nonzi, as at peacer, and that all vessels shall also carry a fixed stern light. The International Rules should also be amended to provide that every vessel navigated in the vicinity of icobergs or ice flows during darkness abould go at moderate speed, having carrial regard to circumstances and conditions. The use of rockets showing red should be restricted to distre

In the interests of the future development of radio-neteorological services, the committee recommends that the existing meteorological service of each administra-tion adopt as part of its programme the organization of a radio service for the coastal waters pertaining to that administration. It is further recommended that meteorological observations be made, at Greenwich moon, whenever a vessel during the preceding four hours has experienced a barometer reading below 30 juches and failing continuously, or has discovered other symp-toms of approaching storm. That class of meteoro-logical information which transcends all others as regards its value to shipping is the storm or hurricau ng, particularly the latter. The committee consid warning, particularly the latter. The committee considers this warning service as promising more beneficial results than the project of distributing warnings to vessels in mid-ocean, and therefore emphasizes the importance of concentrating all means at the command of meteorological services on the development of an effi-cient warning service for coastal and suhtropical waters. The United States Naval Observatory has developed a time service by radio which has proved of great value to shipping, and the committee recommends a counid-eration of the desirability of requesting all governments to establish a like service.

For many years the important steamship lines tra-ersing the North Atlantic Ocean between New York Philadelphis, Boston, and the ports of Europe have agreed among themselves that their vessels should hold to certain prescribed lanes. This plan should be broadened by making the steamship lanes obligatory to steamships. Governments should pass legislation requiring the steamships under their respective flags to strictly to steamship lanes prescribed by them.

In recommending that an International Ice Patrol be established, the committee suggests that the annual established, the committee suggests that the annual responsibility and expense of maintaining this patrol responsibility and expense of maintaining this purely be assumed by each of the several maritime nations in turn, the partol to be conducted in accordance with a general plan to be formulated and agreed to by the several maritime nations concerned at the International oe. The ice patrol shall begin April 1st of each year and continue until the ice ne longer constitutes se to navigation in the sone of the transatiantic a memore to havegation in the sone of the transatinatic steemability lane. At all times during the continuance of the patrol there must be at least one vessel present in the technique section. The committee also recommends that an endeavor be made to reach an agreement with the several maritime nations interested in the transthe several maritime nations interested in the trans-atiantic trade, as follows: The United States to con-time the destruction or removal of deresions in the North Atlantic west of a line drawn from Cape fishel to latitude 34 degrees longitude 70 degrees, and thence to the Bahamas, and other maritime nations to main-tain a suitable vessel or vessels for the purpose of de-stroying or removing deresions each of said line.

#### Electricity

The second of th

Telegraphy from an Aeropiana.—Long distance virapian feligraph experiments recently made from a Bequegeroplane to a ground station at Doual, France, showed
excellent results. The seropiane is a three-exacted fyersetagrafe for the government of Siam. With Moineau
piloting and Engineer Roques operating the viraless
apparatus on board, the seroplane lept on its flight
from the serodrome and sent messages every five minutes
to a land station in the town of Doual. The musical
wave method was employed, and it is olatimed that
messages outle be beard with the seroplane as far as
60 miles off, in spite of the small power used in the
apparatus on board.

Three-phase Italias Ballroad.—In Italy there has lately been put in operation a line of electric road which, although a short one, is of interest on account of the direct use of three-phase current at 42 eyeles. The line is laid from the quarries of Basco to the rail—road station of Bagni in the neighborhood of Rome, and its length is some 7,000 feet. The three-phase current comes from the Laxifiel electric station and is delivered by a line working at 11,500 volts, this being reduced by randformers on the spot to 500 volts for operating the electric railroad. Simal electric locomotives have 30 horse-power motors of special three-phase design on the Brown-Boveri system, which draw \$35-ion rook trains.

Ment Blane Tearist Lines.—The first of the tourist lines in the region of Mont Blane was the electric road from Fayet to Chamonic, which was opened in 1901 and extended some years later to the Swiss Tearist, where it joins the Maritgny-Chabeland electric road, thus connecting the Arve valley with the Federal rail-road. The popularity of these electric road is shown by the fact that it times as many passengers are carried now as in the first period. This great movement led to several projects for mountain lines, and one of these is now completed, this being the steam rack-rail from Chamonix up to the Mer de Glisce, opened in 1904. Another new line partly in service, is the rack-rail from Chamonix up to the Mer de Glisce, opened in 1904. Another new line partly in service, is the rack-rail from Chamonix up to the Mer de Glisce, opened in 1904. Gouter. It is to be extended further up the mountain to a point near the summit. At present the road is constructed only as far as Mt. Leohat. There is also in construction an aerial cableway up the mountain from Palerius village to Col de Midi and Ballée Vlanche. A recent project calls for an electric road from Chamoniz to Mont di Couvercia.

The Julienbuitte Rolling Mills in Germany afford a good example of an iron works which amplicy electric motors almost exclusively, using current from industrial mains. The reversible rolls are operated in this case by an electric motor designed specially for the severe shocks of this class of work on the Allgemiche-Hgases system. Such motors are not supplied directly by the incurrent, but in order to take up the shocks an intermediate machine is used in the shape of an Hgase converter. This group receives three-phase current from the electric mains at 6,000 volts and 50 cycles. It has two separate halves, each being made up of a three-phase motor for driving a dynamo in order to threshose motor from the million of the current supply. In standard practice the two dynamos are coupled in series and furnish current to the two 1,800 horse-power motors of the rolling mill; these two motors having their circuits also connected in series. The present mills furnish 50 to 80 tons of rolled metal per hour. We may also mention that three large motors of 2,000 horse-power size are in use in the tube rolling mills of Elemarckhitte.

Corpuscies Emitted by Alkaline Metals.—Prof. J. J. Thompson brought out the fact that corpusoies are emitted by alkaline metals under the sotion of light, and the effect feebly substate in the dark. The question has been the object of research on the part of various scientists, which Herirot resumes as follows: The action is seen in the two metals potassium and rubidium, and the effect is analogous to radio-activity. Potassium gives of  $\beta$ —rays which are homogeneous and easily deflected by the magnetic field. Their penetration is about like the  $\beta$ -rays of maxim. As regard rubidium, it also gives of  $\beta$ —rays which are slower and rather homogeneous, and as to absorption they resemble the  $\beta$ -rays of radium. It appears that potassium and rubidium is nease smit charges spontaneously which are in part due to ionizing  $\beta$ -rays. The entirence of serve charges could not be seen. L. Dunoger and E. Miller consider this effect to be due to obscure heat rays and not to radio-activity, and is a photo-electric action set up by the infra-red rays. Woodrow measured the potential and considers the action not a Volta effect but a spontaneous emission of corpusales like what redio-action produces. Rowwer, as H. Thirring olimns it to be due to the Volta effect and that such cells set like gairance colls, it will be seen that the question is far from being settled.

#### Trience

Botsaic Garden in South Africa.—The Parliament of the Union of South Africa voted at its last session to establish a large botanic garden at Kirstenhosch, a farm on the Rhodes estates, to the south of Groots Solur, on the castern alopes of Table Mountain. Prof. H. H. W. Pearson has been appointed director.

Zinner's Comet.—A cablegram received at Harvard from Kiel gives the following position of Zinner's Comet as observed by Graff at Bergedorf: October 24.2687 G.M.T.

R.A. 18 hours 45 minutes 53.7 seconds.

Declination—5 degrees 23 minutes 23 seconds.

The comet was visible in a small telescope.

The comet was visible in a small telescope. Free Radium.—Dr. Charles L. Parsons, chief of the Bursau of the Division of Mineral Technology of the United States Bursau of Mines, announces that through the generosity of Dr. James Douglas of New York orty, and Dr. Howard A. Kelly of Johns Hopkins University, twenty-aeven elaims of mining land in Paradox Valley, closurade, have been purchased, said to be the greatest radium bearing ore deposit at present known. The National Radium Institute has been incorporated to work the deposits. The entire undertaking is under the supervision of the Burseau of Mines, and all the radium will be at the disposal of physicians free of charge.

Harvest Weather Forecasts.—This name is applied in Great Britain to telegraphic weather forecasts for forecasts, and the state of the Medical Performance, issued by the Meteorological Office in London every day from June 1st to September 20th, at 2 30 P.M., on the basis of observations taken at the meteorological stations at 1 P. M. They cover a period of 15 hours, taken at 1 P. M. They cover a period of 15 hours, taken at 1 P. M. They cover a period of 15 hours, the conditions are sufficiently definite a "further outlook" extending the period covered by the forecast to two or more days is added. The office issues a special notice farmers whenever a spell of several consecutive days of fair weather appears probable. The service is free, except that recipients pay the coot of the telegrams. The Board of Agriculture and Fatheries has just nested a notice calling the attention of farmers to the harvest

Reselle.—The news that a canning factory in the Philippines has begun to manufacture resells sauce is of interest as marking the initial commercial stage of an industry possessing great possibilities. Resells (Phiscus seddarfia Linn.) was introduced a few years ago into the far southern United States from the West Indies, and has just begun to be cultivated in the Philippines. Until recently the only edible part of the plant was supposed to be the fleshly ealyses, from wheth can be made a sauce exactly resembling craniterry saure an appearance and flavor, as well as surp. jelly, and wine. Lately it has been found that the issues and young stems of the plant also yield palatable products, and the exploitation of reselle has been furthered by publications of the United States Department of Agriculture and the Philippine Bureau of Agriculture.

The Schröder-Stranz Expedition.—The tracio collapse of this expedition in Spitzbergen has already been reported in these columns. Capt. Starral, who rescued the survivors from their ship at Treurenburg Bay, carried them overland to Adven Bay, from which point part proceeded to Norwey and past to Germany. A legal investigation has been undertaken at Christiania concerning the reported dissensions between the Norwegian crew of the expedition's ship and the German scientific staff, which may have had something to do with the deplocation outcomes of the enterprise. Early in June Capt. Starrud set out again from Advent Bay scross Hinlopen Strait and exploring the northern coast of North East Land for traces of Schröder-Strans himself and his lost companions. There is, however, hardly any hope that they have survived.

hardly any hope that they have survived.

Frams Josef Land is one of the three regeons that are focusing the attention of the world in connection with the present active campaign of Arutic exploration, the others being Spitzbergen and the problematical Crocker-land. At the end of August, 1912, a Russian expedition under Capt. Sedow sailed for Franz Josef Land, with the hope of ultimately pushing on to the pole. The enterpties appears to have been poorly equipped and bedly organized, and the start was made dangerously late in the season, especially as the winter set in earlier than usual last year in the Arvito seas north of Europe. After being damaged in a storm, the ship made a stop in Nova Zemblas, and sgain proceeded north Reptember 19th. Early in November rumors reached Europe that the party had been shipprecked. It as total fate is still uncertain, and the question of sending out a rolled expedition is now being agitated in Russia. An alternative suggestion is that the Russian government shall ald in pushing forward the expedition for Franz Josef Land which M. Jules de Payer has been organizing for some time in France, and which was planning to sail before the end of the present summer in the Norwegian season. "Loydran."

#### Aeronautics

An Omnibus Aeropiane. Guseppe Colucet of Boston, Mass., has patented a flying machine which has a plurality of pairs of supporting wings extended from its body and being alternatedy monoplanes and huplanes together with which its uses a proteally mounted substantially horizontal elevating plane. The patent is No. 1,083,108

The Bantson Aviation Station.—The aviation station of Bantzen is soon to be completed, and it will take as good rank from the fact that it lies between Berlin and Vienna, it being proposed to establish an aerial connection between these two capitals before long Upon the inauguration of the new establishment there will be a number of events such as altitude tests and bomb throwing, destruction of railroads and other works.

As Aeropate Propeller with Valve Openings.—
Herbert Prince of New York city, in patent No. 1,008.—
271, shows a propeller for acroplanes which has a number of blades rotating about a common axis and are passages with proted vanes for controlling the passages.

Rack gearing is provided for opening and closing the vanes, and a cam mechanism operates upon the gearing to open the vanes of one blade while it closes the vanes of another blade. Means are also provided for varying the action of the cam goaring.

Moreau's Sacrifices.—Moreau, the French inventor, who rewently won the Bonnet prize for flying with his hands off the controls of his machine, has an interesting history. He is employed by a large printing house in Paris. Most of the money that he earns is devoted to avastion. His family and himself must content themselves with the hare means of subsistence. Despite his modest insome he has done wonders in designing his automatically stable machine. It is to be hoped that the winning of the Bonnet prize funds by Moreau will induce either the French government or wealthy French patrons of avastion to take an interest in him.

A New Schittic-Lanz Alrahlp.—The second Schittic-Lanz airchip of the Gorman army, known as "St. II," and designed by Prof Lanz, is now incaring completion at Mamheim The new airship contains 847,000 cube foct of gas. It has five care, one for the commander in front and four for the crew. Two of these four care are loosedy suspended in the center line fore and att, and the two others are fixed rigidly in the middle on each side of the center line. Four motors, three May-bach and one Daimler, drive the airship. Two propellers are connected with each motor. The speed of the vessel is estimated at 45 miles an hour.

The Elffel Tower Weather Reports.—Military semmatic are now recoving weather reports from the Elffel Tower wireless post, and this spenal service was started running a short time ago. Each day there are sent out two weather bulletins, at 10 A. M. and 5 P. M., and these are received by all the military wireless stations, being spenally drawn up for the needs of army seromatis. The chief officers at each station will be thus able to draw up weather charts and to interpret these according to local conditions. It was upon favorable notice from the Tower that Dubonnet and Rumpelmayer made revent balloon trips, and the ariship "Adjustant Unesnot!" started on a long voyage from Paris. Guillaux made his acroplane trip to Ham-

burg and Lotort left for Beris reopens only or age and with a burg and Lotort left for Beris representations. The British Airship "Eta."—The "Eta," the least the royal arcraft factory, is now undergoing tests. The shape is a modified Parsawal in type. The eapmenty is 100,000 cubic feet. There are two radial statuonary 160 horse-power engines set on opposite axides of the ear with their axee placed transversely. As in the Parsawal airship servicing propellers are used. During one of her trial flights, the "Eta" went to the assistance of naval airship in C. which had broken down The novel experiment of towing the dushibed airship in two depths are used. In a reccont number of Flight's a photograph was published which shows the dushibed airship in two of the "Eta." A difference in level of about 600 feet was maintained in order to avoid all chances of fouling the ruddler gear.

Perventing the Dreaded Back-Fire.—One of the most formulable and greatly dreaded causes of accedents in flying machines as back-fire in the carburetor. As a case the result of an attempt to solve this seconds problem an ingenious device has been invented by J. Holt Thomas an ingenious device has been invented by J. Holt Thomas in figure to the present does not present does not present to prevent back-fire, but is intended to prevent damage by putting out the parts of the machine. A two-way cook on the carbureter is connected with a lever normally held down by a fasible plug which made at a temperature of 140 deg. Fahr. A plug fusible at any desired temperature may also be used. When a back-fire occurs the plug is melted and this allows a small steel spring to set upon the lever, closing the tuel line to the supply tank. It also opens, simultaneously, a vent which allows the fruel remaining in the earbureter to be drained to a point below the feedings or to any point outside the danger or any point outside the danger on the set.

## The Jungfrau Railway

#### A Great Engineering Feat

On February 21st, 1912, the tunmal beneath the "Monk" was completed to the Jungfran Pass, and early in August the Jungfran Pass station, the highest rallway station in existence, was opened to traffic

In 1893, when the Sales millions king, Adolf Gaute Zeller, proposed to construct a unitival to the Jungfan hydroling beneath the Eiger and the "Monk," the scheme was deemed visionary and impracticable Work was commenced in 1893, and in 1896 the first section was completed and put into operation. This section of 2 kilometers (1.2 miles), mostly above ground, connects the Eiger glacier station (elevation, 2,223 meters, 7,321 feet) with the Swigs railway station at Kieline Schedligg (2,004 meters; 0,472 feet). At the Eiger glacier begins

the great (name), with a meen gradient of 23 per cent, complied to its temporary termines at the Jonatran Pless At a distance of 44 kilometers (27 miles) from Kleine Scheiding and an elevation of 2,908 meters (18,408 feet) the tunnel grazes the northern wall of the Eiger, and here the rock-heen station Eigerwand, which overhooks Grindelwald at the mountainty foot, was opened to traffic in 1963. From this point the tunnel follows a curved line to kilometer 57 and there expands to form the station Eigeneer (elevation, 3,101 meters; 10,308 feet), which commands a wide thew of the glacter and has been visited by thousands of couriests since it was opened in 1905. This station was the provisional terminus of the fine until last August

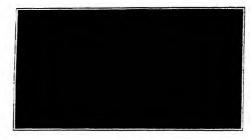

Work on the tunnel section of 3.5 kilometers (2.2 miles) between Elemeer and the Jungfrau Pass was commenced in 1997, by the executation of a large machine room and a interal gallery opening on the mountain side, for the removal of evenwated material. For 3 kilometers (19 miles) from this point the tunnel runs in a straight time under the "Monk," with a gradient of only 6.3 her cent, so that tooth radia are not needed. In 1911 the work of ventilation and removal of material was facilitated by opening a lateral tunnel 200 feet long to the vide of the "Monk." Here the tunnel resources the gradient of 25

tunnel resumes the gradient of 25 per cent, which is maintained up to the Jungfran Pass (elevation, 3,457

meters, 11,341 fort1
Although the work was carried
on day and night, the great elevation and the hardness of the rock
limited the daily progress to abant
12 feet. In some sections the grebsresisted the hardness the solidity
made all lining of the tunnel superthous. The thun ridge which forms
the Jangfran Pass was approached
with the utmost caution as it was
foured that the glacler night he so
deep than the tunnel night near

visitors can wander over ics, snow and glacters and enjoy skating and ski running, without danger or heroic exertion. A sledge roof over the Aletch glacter has been suggested, and even Guyer-Eeler's jocaliar proposal to maintain a regular summer service of dog sledges between the station and the distant Konkordia club house may be carried out.

The extension of the tunnel and railroad to the sum-

The extension of the tunnel and relitond to the sumnit of the Jungfray, about 2 mine leyrond the page, will not be undertaken immediately, as if has been dound most profitable to proscute the work by successive stages. The original plan contemplated the completion of the whole line in seven years, with an outlay of about 8 million frames (\$4,544,000), but more than 10 million frames (\$4,544,000), but more than 10 million frames (\$4,544,000), but more than 10 million frames than 1,000 frames per meter. The financial burdens have been materially lightened by the earnings of the completed sections. Furthermore, the concession for the section between the pass and the summit of the Jungfrau has expired, and the Swites advocates of "conservation" oppose its renewal—unwisely, because the railroad will not injure the Jungfrau, but will merely make it accessible.

The ascent to the Jungfrau Psss on foot is seldom made, as it is one of the most dangerous of Alpine tours. The view from the pass is wonderfully beautiful and impressive. To the north it extends far beyond the

ours. The view from the plant is wonderruity obsurbers.

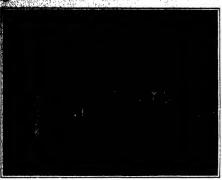

To the north it extends far beyond the gladest, which here makes it a tumulituou descent to the valley. It includes the wide northeastern plain of Svitaeriand to the distant bills of the Schwartsward and, in the foreground, Interlaken, Lake Thun, and the Lautsbramann valley, in the seat the view is cut of by the upper pass and the sharp-angeled pyramid of the "Monia," which rises almost vertically to an elevation of 4,105 meters (1,304 feet), while in the distance appears to the peak of the high of the plant of the peak of the high of the peak of the plant of the peak of the peak of the peak of the plant of the peak of t

The view to the south is thoroughly Arctic. The Aletsch, greatest of Alpine gladers, stretches down toward the Rhone valley, figured by the snow-clad slopes of

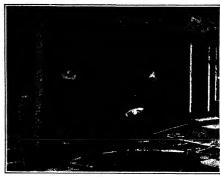

the "Monk" and the Jungfrau. The eye fluds no green spet, no sign of life, and no human trace, except the Konkordia hut in the far dis-

## The Daniel Boone Idea in Education

A School System Based on Voluntary Muscular Work

On the outskirs of La Porte, a small manufacturing town in northern Indiana, a group of thirty-five teachers and one hundred and forty hoys are making an experiment in education. They live in a perfect or equipped school, located in the heart of an Nöostre farm. These beachers are all "cultured" in the conventional sense of the term; for they are the graduates of isading American or European cities. Nearly all they are the graduates of seding American or Well-to-do partonis and have known all possible comforts from their early days. Neither marries nor pupils, however, bear any external signs are any order of the service of the

ance still suggestive, so far as possible, of the forests from which they have spring.

Like many other modern improvements, the Interlaken School is a proriest against accepted ideas in American education. That there is something fundamentally wrong in the present methods of bringing up children is now a settled conviction among tilinking people. Ferhaps that is due for the fact that life is now a very different thing from what it was fifty or a hundred years ago. Instead of walking we ride in automobiles or trolley cars; instead of cultivating our own food, we have it left at our doors in packages or cans; instead of weaving and making our cothons, as most American families did a inunored years ago, we buy them at stores. All these things mean progress; but every step forward in invention is also part of the general 'conspiring the them."

Seventy-by wers ago eighty per cent of our Americans lived upon the fings. The by rose early in the mortules and did the "chores," In spring he plowed; in summer he performed his task in open air work on the farin; in the settman he heiged to harvest the crops. In all cases he did read work—purposeth work that added to the world's wealth. Now the great majority of bors live in the town. Peop hope and rich boys spend but a faw hours at school, more or less willingty; and what his order is over they are left to theif own devices. The fact cannot be secaped that the country buy is constantly using his hands, while the city boy is not. Sided city hope, send dispose with their height shoughter, and rill purfore, thair "members," daths "rortime distinct control that "rortime daths" country but distinct city hops, send dispose with their height shoughter, and rill purfore, thair "members," daths" rortime distince—accept that

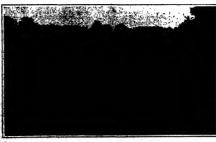

BOTH THE WAS ASSESSED.

for the purpose of esting and dressing. But the human hand, after all is said and done, so far paramount importance. It was not until man began to use his forward members for other purposes than locomotion that he really began to progress intellectually. As long as the infant has to lie prome, its mental progress is extremely limited; as soon as it begins to creep and walk, its infellectual life begins to dourish.

We sain practically all our knowledge by the use of our hands and the rest of our muscular waten as infants. There is not a single one of us with would have any first-hand knowledge of iron or any other metal unions we were able to take it into our hands Our cree fell us that it is gray in color, that it is crystalline, that it as urface is smooth All these thinse, however, might be equally true of painted wood I is only when we take the metal in our lands, attempt to bed and to break it, that we really understand its nature. Not only do our muscles enlighten us as to physical facts; they interpret the deepest cunctions of the sout. Pleasure, pain, agony, remores—all those feel-

Summer on the lake.

ings find their appropriate spokesmen in facial expression.

It is a fact of the greatest significance for educators that the function of speech is localized in the third frontal left lobe of the brain, in close proximity to the motive center that regulates the hight hand Left landed persons have the center of speech in the right lobe. In other words, the faculty of speech is closely related to the faculty that courted is the mad. Both developed in the same parts of the brain. Teach a left-handed child to use its right hand and as due case of stammering sometimes results. The two highest attributes of must—speech and the hand—seem to be really a part of one and the same intellectual faculty. Any attempt to educate a child without completely training the hand is fundamentally wrong

Clearly, what we really need is something like the hand training that our boys used to get upon the farm —not the similarity of manual training such as most educational systems have introduced in recent years, in the old days the school could properly neglect this

able of education and leave it to the home but, as we have said, the indefashioned home has disappeared. These the modern educational system, therefore, finds some indequate substitute for the muscular training of other days, its graduates will be only half men or half women. Not only is the body stunted, but the mind for the mind liself really grows and develops as a result of nuscular and especially of manual training.

It is to supply this need that the new schools have been established in Europe. In the founding of the Interluken School the basis for an extension of this system to the United States was laid.

In the creation of the Interlaken School the logs have fived over the experiences of the early American pioneers. Ten years ago the site of the school was a primeval wilderness. Early in June, 1910, the Interluken boys, a hundred and twenty strong, invaded this neglected waste. arised with axes, corpeneer tools, and above all, youthful enthusiasm for work above all, yournit entities on recovers and new expertences. The school had its inspiration in the principle that boys should regain the unique intent which their grandfathers possessed of doing things for themselves. What more approbeginning could they make the that of erecting their own school buildings with their own hands? That spring the hoys spent making plans, calculating, estimating material, devising schemes of decoration, and outlining the work one was forced to participate; for the of theory is to make the work purely voluntary. The plan was to establish a summer camp on the site of the future school. All who wished to take their vacation in this way were invited to come (Concluded on page 370)

#### The Encyclopedia Americana Enjoined from using the Name "Scientific American"

S OME years ago the representative of a publishing house in New York called at the office of the SCHEN-Onouse in New York called at the office of the Scientific Americas and ind before a representative of the company a plan for the publishing of an encyclopedia for the American people similar in scope and design to the Encyclopedia Britannica, only that it should be planned and carried out in such a way as to be of special value and interest to Americans. The project secured to possess merit, and a number of interviews followed, during which is held of the Scientific American followed, during which is not of the Scientific Americans. CAN Was sought in preparing material for the new work and finally one of the members of the company was insited to act, but entirely in his individual capacity, as editor in chief. A corporation was finally formed under the laws of the State of New York to carry out the work of publishing the Encyclopedia and placing it the work or judicialing the Encyclopedia and picking to input the market. This company was called the Ameri-cans Compan. A contract was finally entered into with the SCIENTIFIC AMERICAN by which the literary end of the work should be conducted in the name of the Scientific American Compiling Department, and in the contract which was entered into, which was for a period of one year, and which was made renewable year by year, the Encyclopedia was sold to subscribers together with a year's subscription to the Scientific American. nd in order to establish the connection the SCIENTIFIC AMERICAN conferred upon the corporation the right use the title "Scientific American Compiling Depart-ment."

All the husiness of publishing the work and of place ing it on sale was conducted by the Americana Com-pany. A notable list of contributors was obtained, and from a literary point of view the work was satisfac-tury. For a long time the arrangement worked satis-facturily, but in the course of events complaints were received at the office of the Science 12 Agracas in which it was charged that the representatives of the which it was charged that the representatives of the Encyclopedia had been quilty of misrepresentation, and it was found that various abuses had crept in, which Munn & Co seemed powerless to have corrected. Every effort was made to correct such mistakes and abuses, and, finally, the publishers of the Eucyclopedia were notified that unless such abuses could be stopped altogether, the arrangement would be terminated

About this time it was discovered by Munn & Co that the publishers of the Encyclopedia were making plans to publish a Biographical Encyclopedia as an addendam or appendix to the main work. People of prominence, some of whom were well known to afficers of this company, were invited to have their portraits published in this work, but they were at the same time luvited to subscribe a generous amount in order that their biography might be embellished with a steel engraving of themselves. It was discovered that in some cases the canvasser who solicited those contracts held himself out to be a representative of the Scientific American When this fact became known it was de clided that the arrangement could not be continued and the officers of the company were notified that owing to the various abuses which had arisen, the name of Scientific American Compiling Department must be withdrawn from the Encyclopedia and from all litera ture being sent out by the company. It was also dis-covered about this time that a new corporation had been formed which was known as the Americans Company of the State of Muine. This company had a capitalization of \$1,500,000, and amountements appeared in the papers and magazines stating that the stock of the company was being offered to the public. Minin & Co pro tested against the issue of this stock, and insisted that the use of the title Scientific American in conjunction with the Compiling Department must be discontinued. A number of interviews took place between the officers of the two companies, with the final result that the officers of the Encyclopedia Company refused to discontinue the use of the title Scientific American Complling Department in connection with their car and as a result the contract was terminated by the complainants at a meeting of the board of directors of Munn & Co. held in May 1911, and in June, 1911, a resolution was passed directing the officers to engage counsel to bring suit against the Americana Company to enjoin them from using the titlo Scientific American, either in connection with the words Compiling Department or in any other way, and they were further directed to notify the Americana Company of this fact in order to give them a final opportunity of withdraw tng without the necessity of a law suit.

No definite answer was received to their comm

cation, but a few weeks later it was learned by the officers of this company that a new stock corporation was being projected and carried out by the Americana people it appears that a corporation had been form by them, but without the knowledge of the officers of the Scientific American, under the title Scientific American Compiling Department, with a capital of \$2,000. In the autumn of 1911, after notice had been served of the impending injunction and after the contract had been terminated, the stock of this company was increased from \$2,000 to \$2,000,000, and by offering some stock as a bonus the stockholders of the An cana Company were induced to exchange their stock in the Americana Company for the stock of the Scientific erican Compiting Department

Papers in the suit were served upon the defendants i December, 1911, and the suit was tried in July, 1912, before Vice Chancellor Emery of the Court of Ch of New Jersey. Notices warning the public of the suit were published in the SCIENTIFIC AMERICAN in 1911 and 1912 at regular intervals.

1012 at regular intervals.

The option of the court has just been handed down, and it is sweeping in its character. It is very long and covers every phase of the case from the very beginning. It consists of over fifty pages of legal cap, or some 15,000 words. The history of the case from the beginning is creedily sone over and much apecs is given to unraveling the complicated relationship of the various companies under which the Encyclopedia was operated, which conducted of at least four different corporates. tions with overlapping interests and responsibilities. The opinion of Vice Chancellor Emery states:

The opinion of Vice Chancelor Emery states:

"The main object of the bill is to epidot the use in any manuer of the name "Scientific American" by any of the defendants in connection with the corporate title or with any of their publications. The complainants in their state in the grounds:

"First. That the right to use the complainants of their publications are selected as a state of the stat

"The bearing of the matter of the extent of proof of confusion, loss or injury, or actual damage, on the main question now at issue, the further continuance of the name. "Scientific American" in connection with the name of the property of the same of the name of the nam

to the present connection of complainants with the work and responsibility of some kind therefor.

"Lending the running of the contract and parity by reason of the Impression of complainants connection with the work given by agents soliciting subscriptions, confusion occurred which required attention by complainants to chains involving financial responsibility securities them, as well as responsibility from a literary or editorial standpoint. These claims, based both on financial and literary responsibility, were as frequent—every two weeks on an average—and of such a character as to impose upon complainants the burden of responsibility of the contract of the co

"This contraion requiring attention and action on the part of the compinimants to avoid responsibility, has ulready, in my indement, ensued an injury and damage to the compinimants in carrying on their business as publishers of the Neutrantz Augusta, Surgespaper, and application of the Neutrantz Augusta Surgespaper, and in the present and future publications of the "Americana" they are entitled to equivable relief as the only effective relief. The confusion results primarily and directly from the use of the compisionars well known and long established manne Sometripto Augusta Surgespaper, and the property of the compision of the surgespaper of the compision of the Schutzpier American has made a specialty for sixty years.

"The public to whom the work is offered for subscription, are entitled to know that with the publication and placing on the market of the present editions of the "Americana" the publishers of the Schuzzure Americana have no connection or responsibility of any kind, financial or literary. To compel, or attempt to compel, sortie explanation by soliciting agents, that the publishers of the Schuzzure Arranco are not connected with a continuous continu

method of insuring to come is that of enjoining altoge-name "Scientific American" is that of enjoining attogether the fightles aname "Scientific American" is the corporate also enjoining its use in the publication or of the "Americana" of the editions of 1813, future editions except as hereafter stated."

The use of the title Scientific Americ partment was not only desirable, but the most conveni-ent method of bringing before the public the literary etion of the SCIENTIFIC AMERICAN with the compiling of the Encyclopedia, but when the publishers of the former discovered that this name was being sxted in a manner not covered by the contract not intended at any time of the negotiations, and that they had no control or power to correct these abuses; when it was discovered that the name of the Schmither when it was discovered that the name of the SCHRYING ARMICAN was being used to promote the sale of a blographical work of which they had no knowledge or interest; and when, lastly, it was found that the stock of the Encyclopedia was being placed upon the market under the name of the Scientific American Compiling Department, the publishers of this periodical having no interest in or control over these transactions, the only course left was to bring suit to enjoin the use of the name "Scientific American" in any and every con-

nection with the sale of the Encyclopedia.

The decree of the Court was entered on October 28th,

#### Between Life and Death

NABIOSIS, a state where all vital functions of the A NABIOSIS, a state where all vital functions of the A organism are suspended, without however death occurring, has been known for about 200 years, in the case of some of the lower animals, which can be dried and restored to life, even after a considerable time,

merely by the action of moisture.

A Russian scientist, Prof. Bachmetief, has tried to A Aussian scientist, Froz. Hackments, has freed to ascertain whether phenomena such as these could not as well be observed in the case of higher organisms. While examining insects at decreasing temperatures, he found that the temperature of their body, after reaching the freezing point of water, would gradually fall as low as 5 deg. Cent. (in the case of some species even 7 deg. Cent.), in order afterward to rise one de-

gree and esentually to continue falling regularly and gradually. Death would only occur at 10 degrees. Prof. Bachmetlef first thought death to be due to the freezing of humors, but be soon found that the humors of insect bodies already frees at 5 deg. Cent., any vital function becoming impossible at this temperature. At temperatures intermediary between this porature. At temperatures intermentary between this point and the lethal temperature, a strange condition of anabiosis is produced, the organism being as it were between life and death. Animals in anabiosis have been repeatedly restored to life, even after a considerable time, by a gradual rise in temperature. This conable time, by a gradual rise in temperature. This condition could be fitly compared with that of a clock with stopped pendulum, the mechanism of which could be at any moment, started again by a slight impulse given to the pendulum.

to the pendulum.
These experiments were then extended to the case
of some small-sized mammals (bats and white mice),
which by the application of artificial respiration, could
be reduced to some sort of lethargy, their body standing temperatures too low otherwise to be endured (0
deg. Cent., and less). Further experiments are to be made on higher animals.

made on higher animals.

The main purpose of the experimenter was to find a safe cure for tuberculosia. Applications of a mainly practicat character, calculated to revolutionise some of our habits, are however likewise to be made. As regards the case of tuberculosia, it is well known that the microbes producing the maindy will die or lose that powers of reproduction, on being submitted for two or three weeks to a temperature of 5 deg. Cent. If say, 8 deg. Cent., all Koch microbes would be arfely killed or else rendered innocuous. On the other hand, killed or else readered innocuous. On the other hand, Bachmetfel is of the opinion that it would be advan-tageous to reduce to Enablosts, without any need of receding them, such domestic animals as are unproduc-tive in winter (bees, sheep, etc.), as well as those which are to be transported to considerable distances (cattle, fowls, fish, venison, etc.) in order to restore them to life whenever required. In order to begin with something practical, Bachmetlef has applied his od with excellent results to the long-distance teams

A New Scotista Antarettic Expedition is being organ-ised. Its plans include the establishment of a base in Coate Land. A part of the expedition will winter here, and utilimately endes vor to cross the Antaretic southeast to Ross Soa. Meanwhile, the rest of the expedition, after returning to Australia for the winter, will, if possible, effoct is landing at Vindifurdo Sound in order to meet and sid the party evosing from the opposite side of the contineant. Extensive coaseographic re-exambnes are to be carried out in the South At-lantic.

# The Fire Control Platform of a United States Battleship

How the Telescope Sight, the Range Finder and the Spotter Co-operate to Secure Good Shooting

By J. Bernard Walker

If we were asked to name the one particular mechanism to which more than any other is due the marvelously accurate shooting of heavy guns at the present time, we should unhestiatingly pronounce in favor of the betscope sight. Remove the telescope sights from the batteries of a modern warship, and the ranges would have to be decreased from twelve thousend to three or four thousand yards, and the shooting would be very indifferent at that. The modern system of fre-countrol is very elaborate, highly scientific, and dependent for its remarkable results upon the co-operation of many delicate instruments and the combined observations of several highly trained specialists. Remove from the system any one of these instruments or any one of the sen concerned in its successful operation and the result would be impaired somewhat; but remove the telescope sights and you remove the whole thing.

Twenty-two years ago there was not such a thing as a tenecope sight stateshed to a naval gmin in the whole world. Ships' guas were using the old open sights, the one at the breach being adjustable to give the proper elevation to the gun. While activing to keep his eye in such a posttion as to maintain the two sights in line, the gunner awaited the critical moment when the roll of the ship brought this "line of sights" onto the target; and then he fixed the gun.

About this time, or to be more exact, in the spring 0, a young officer of our Navy, L Admiral) Bradley A. Fiske was aboard the U. S. S. "Baltimore," watching a test of his new electrical rangefinder. During a delay in the firing, due to a flock of schooners having got in the way, he amused himself by looking at the schooners through the forward teleof the range finder instrument, and noticed how definitely the cross hairs of the telescope moved across their sails with the gentle rolling and pitching of the "Baltimore." The thought suddenly struck him that anybody could fire all the guns in the broadside at that place where the telescope stood, and hit the target every time, by setting the telescope at the angle of depression equal to the proper angle of elevation of the guns, leaving the guns parallel with the deck and firing when the roll of the ship brought the cross hairs on the target This line of thought ultimately led Lieut. Fiske to de sign a telescope which could be mounted on some part of the gun carriage that did not recoil, though it turned with the gun, the telescope being capable of depressi with regard to the gun through a number of degre corresponding to the degrees of elevation for a given

The idea was posh-poched, but the invention was patented nevertheless. A suitable telescope was then bulk and applied to a gun on the gunbost "Yorktowu," to which Lieut. Fisic hab been assigned; and on September 12th, 1892, during practice carried out at Unalaska, Alaska, in competition with guns fired with the open sights, the new telescope sight proved its great superiority, to the astonishment of all on board, except the inventor himself.

The advantages of the tolescope sight are many: It is shown exactly, instead of inexactly, what the gus is pointing at: it swooderfully clears up the target; it is enlarges the field of view over the old system some four or five times; it does not recoil with the target, and therefore the gus pointer may keep his eye constantly that the eye-piece; and, lastly, used in combination with the powerful and rapid gus elevating mechanism now employed, it enables the gus pointer may be sharped to keep the cross section of the section

employee, it enables the gain pointer to keep the cross share of the telescope, constantly upon the target ship. We mentioned above how it occurred to Lieut. Fisher that a telescope, set at the proper depression for the range, might be used at some definite position in the ship, and that from this startion the whole battery might be laid in parallel and fired sizualizanceshy by electricity, when the roil of the ship brought the telescope sight on the target. In 1890, Lieut. Flake secured a patent on a method embodying this lidea, and this method is what is known in modern days as "director fring." Some experiments were made in the British navy about the time that Flake secured his patent. The idea remained dormanty for many years, but it has labely been taken up, and throught to undoubted execution of the start o

. Due over Navy has developed its own system of direction distriction distriction of the details of which are of course Dopartheest exercis. Such a system has been installed and recently tested on a vessel under the supervision of Lieut. Com. B. A. Long.

Director uring is certain to occume general among the navies of the world; and it is gratifying to know that our Navy, to which modern naval gunnery is indebted for the telescope sight, has secured excellent results in its first test of the latest improvement

using in the tensors sight, has enemed exceeding a suits in its first best of the latest improvement. These existing confidence, such gen is elevated by its own gen-pointer, who, with his over at the telescope and his band on the second such as the second such as the his second of the second such as the second such as the high second such as the second such as the second such as the naily are second; would see the second such as the second as above by the fact that the 12-gun battleship "Artnasa" recently returned to her home port. New York, with the following target practice record for one of trurets: During one of the runs, the two 12-inch guns of No. 4 turres exceed six hits in 57 seconds, the time being taken from the start of the powder and shell from the ammunition room below to the firing of the less about the six.

This fine work was done during target practice held for the purpose of selecting run pointers, that is, the men who elevate and fire the guns. The 12-inch gun is designed for a muszle velocity with

The 12-linch gus is designed for a massic velocity with full service charges of 2,800 feet per second; but for this practice she was using reduced charges giving a lower mussic redocity. The range was short; but because of the low velocity a furity high sight her range was necessary. Furthermore, the target was very small, being only one serventh of the area of the target used in lettle practice at 10,000 yards, and it represented only about one fitting to the total projected area of a bat-

The 12-linch gan is such a remarkably accurate piece that, if the distance to the target is known, and the sight setter and pointer are expert, the shell will find its way unerringly to the built's eye. It will be understood, of course, that the three conditions named are not the only conditions affecting accuracy; since there must be taken into account the condition of the powder, the temperature of the gun, the wind, the density of the atmosphere, and other conditions which have their effect upon the flight of the projectile. But, broadly peaking, it may be said that if the distance, the sight setting and the pointing are accurate, a built's eye will

Deficient, then, the fundamental necessity is to know the range or distance, and this is secured by the cooperation of two agesides—the range finder and the spotter. Now severy school boy knows that the distance to an inaccessible object may be determined if we know the length of the base line and the two angies at the end of this line between the bese and the distant object. Thus the surveyor measures a bess line with his stoci laps, seds up his transit at the ends of this line, measures the angies, and then, by a quick calculation, is able to determine the distance from the base to the object. Now the range finder is a most inputious instrument in which the bease line is measured, the angies observed, and the mathematical problem worked out, all surematically by the instrument tief, the resulting distance

to the object being indicated by a pointer on a scale.

The range finder shown on our front page engraving contains two object glasses, one at each end, directed toward the distant ship, and on the opposite side of the tube, at its center are the eyepieces for the ob The image of the ship that is received through the right hand object glass, is seen by the observer in the upper half of the field of the eyeplece. The image coming through the left hand of the glass is seen on the lowe half, and the images represe t. respectively, the upp and the lower half of the ship. The right hand of the observer holds a little thumberrew, which serves to move transversely along the axis of the tube a prism sects the rays of light that have be flected by the prism at the end of the tube, and are mass ing to the central eye-place. When the range finder is "out of focus" so to speak, the two halves of the ship out or rocus so to speak, the two harves or the smill will not be properly slighted, and the observer bring-them into focus by turning the thumbacrew. When signment has been secured, the observer looks at a small horizontal scale on which the exact distance of the ship is indicated by the triangular pointer shown

The range, as thus determined, is telephoned to the firs control station below deck, where certain currections are made, the corrected range being then tele-

phoned to the sight setter at the gun.

Even though the sight setter sets his sight har correctly, as: the pointer first when the horizontal wire of his telescope is exactly upon the center of the target it may yet happen, that because of, let us say, refraction due to the condition of the atmosphere, the full and

spinsh of the shot may be a couple of bundred yards over or short of the target, necessitating a further correction. This correction is made by the spotter—the officer shown in our front page curraving with glasses in his hand, and telephone champed over his cars Through his glasses he estimates that the spinsh is, each short of the target; and immediately he calls into his telephone monthplece, "200 mj" meaning that the sight bars must be raised to an extent corresponding to 200 yards in rungs. From this time on, during the firing, the judging or correction of the range is in the hands of the spotter.

## Electrolytic Production of Oxygen

C ERTAIN industrial applications of oxygen, such as autogenous welding by the blowpipe, require the use of a very pure gas, owing to the fact that impurities cause a lowering of the flame. The production of oxygen by distilling liquid air does not allow of entirely eliminating the nitrogen, and the best rectifying apparatus give a product which still contains from 1 to 14 per cent of nitrogen. The electroivile process appears to be better for this purpose, and it allows of more easily obtaining oxygen at 99 per cent or even more. The improved apparatus now produce crude gases such as oxygen at 96 to 98 per cent and hydrogen at 98 or 99 per ceni, and the gases are then fled. In the Schuckert electrolyzer which is des for this use, the gases coming from the electrolysis are collected in bell-shaped vessels. The elements of the apparatus are constructed so as to support variations current within the limits of 2.5 to 4 volts without producing any detrimental effect on the purity of the gas It is found that the oxygen which is produced in this way does not contain more than 2 to 4 per cent hydrogen for the crude gas, and the hydrogen contains less than 1 to 15 per cent oxygen. The mixtures of the two gases occur to a slight degree owing to the movements of the bath and the diffusion of the gases, and the amount of impurities increases as the electrodes come nearer logether. But as it is required to keep the electrodes rather close together in order to reach the maximum yield of gas, some degree of mix-ture of the gases must be allowed. A remedy was sought by patting in porous partitions in cement or asbestos, but these required much attention and raised the upkeep cost.

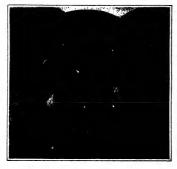

The iron anodes are protected by a deposit of mag-netic iron oxide which prevents their being attacked by the oxygen. In the bath, the presence of impuritie such as chlorides, sulphates, and the like is to be avoided, as they would give rise to ferric hydrate partly in suspension in the liquid and in part deposited on the cathode, which would require an increase in voltage. Caustic soda is used in practice for the bath, this not containing more than 0.1 per cent of nati, this not containing more than of per cent of sulphates, nitrates or chlorides. The gases produced by the apparatus are sent at first through a vessel containing coke which is sprinkled with water, and here the particles of caustic sola which are drawn over are absorbed. To eliminate gaseous impurities. istion is set up with a part of the oxygen and the 2 to 4 per cent of hydrogen which it contains, and the hydrogen in inrn is purified in the same way ing out the oxygen This action is produced by passing the gas through a silver tube which is heated to low ess by an electric current passing in a platinum spiral. The tube contains pumice stone treated with palladium. This method has the advantage of preventing explosive mixtures which might be formed, for instance, should the poles be accidentally inverted, and such mixtures cannot reach the gas holders. heating is done by the current from the main apparatus, the heater starts up as soon as the gas flows.

Practically all the expense in the electrolytic process in the code of electric current, as the apparatus is automatic and needs but liftle attention. All that is needed in to add a certain amount of water one day, this being 2 cubic feet of water per foot of oxygen or per 2 feet of hydrogen. Circumstances devide which is to be preferred, the air distillation or the electrolytic method. The air process needs a less amount of power, but requires constant watehing and experienced labor, it being in fact more expensive than the other when it comes to small plants. Besides, the starting up of the siparatus requires two or three hours, in which time it is not productive and consumes power, so that such plants should be run continuously as much as possible. On the contrary, the electrolytic apparatus can be started and stopped at any time without draw.

# The Completion of the Los Angeles Aqueduct

Bringing 265,000,000 Gallons of Water Per Day 234 Miles From the Sierras to Los Angeles

By Henry Z. Osborne, Late President Los Angeles Chamber of Commerce

Section of an eleven-foot steel siphon.

A drive through the aqueduct.

Smooth-finishing a conduit.

O WINN River Valley geographically is more of a Novala valley than one of California. The river from which it takes its name, in its southern course parallels the main range of the Sierra Newday, and has its source in and derives its waters from these grand mountains. The suowfull is extremely heavy in the high eastern side of the Sierras, and nearly wery canyon that leads steeply down to the plains of Newdad and the adjoining Tayo and Mono counties, in California, carries fine streams of water throughout the year, which streams are veritable rivers in the spring and summer months when the winter snow are melting. Thirty-five such streams empty into the Owens Iliver from a fariange area of 2,500 square miles. The length of the river is about 150 miles. Its waters are made up integether of the snow waters from the Sierras. The valley itself is from two or three to ten miles wide, and unificient vater flows in the river to irrigate all this valley, with an overflow into Owens Lake, area of Square miles, where it performs no useful service, of sufficient volume to supply a city of two millions of people with an ample quantity for domestic

It was to this grand source provided by bounteous nature that Los Angeles turned, when it was foreseen that in the course of its rapid growth there might be a shortage in the indiscensable water sundy.

A former city engineer and subsequent mayor of Los Angeles, Fred Eaton had spent some years of his ceriber life in the Gwens River Valley of injo Countr, and to his aftert mind probably first occurred the idea of Owens River as a source of the permanent water supply of Los Angeles He presented the subject to the Board of Water Commissioners and to Chief Engineer William Muhollanda, and the latter was sent with

Building a reinforced concrete siphon.

Mr. Eaton to look over the ground. Upon his return a favorable report upon the project was made by Mr. Mulholland, who in 1905 prepared plans and estimates for an aqueduct to bring 260,000,000 gailone daily to the eity, the cost of the work to be \$23,000,000. The plans were approved by a board consisting of John R. Freeman, James D. Schuyler and Frederick F. Shearns, and the citizens by a popular majority of 10 to 1 voted in favor of construction, and work was begun in favor of construction, and work was begun.

and the citizens by a popular majority of 10 to 1 voted in favor of construction, and work was begun.

Two years were exhausted in finding the best and most feasible route, which was often changed by Mr. Minholland and his chief assistant, Mr. Lippincott, for economic or other good reasons. Fourteen months were required for the enormous preparatory work. So that, with the exception of some work at the Distabeth tunnel and at the intake, the actual construction work of the aqueduct commenced in October, 1008. The wisdom of thorough preparation even at the cost of considerable time was fully vindicated by the rapidity and certainty with which it proceeded from that time.

The Aqueduct.

The intake of the Lee Angeles aqueduct, which is constructed of concrets in the most solid and substantial manner, is situated thirty-live miles above the mouth of the Owens River; this to insure against the possibility of sikal solutions. Its elevation above see level is 8.912 feet. The dimensions of the aqueduct vary greatly on different parts of the work, depending upon the physical nature of the country through which the water is passing. The first 22 miles is a canal, 62 feet wide at the water surface, 88 feet wide at the bottom and 10 feet deep, uncommanded, and at a slightly higher elevation than the river. This canal was excavated by three electric fireders.

At the Alabama foot-hills the aqueduct is conducted

Eastern slowe of the Sierras, the watershed of the Owens River.

Spag the anoministical, pisseing Owens Lake on its sweigen side and about 200 feet above the surface. This part of the aqueduct is converse lined, 30 feet wide, 12 feet deep and 35 miles long to the Hairwe reservoir, the fixed of the five great storing beatins. This upper portion of the aqueduct to Hairwe reservoir, is the only portion uncovered. All the remaining conduct is conversed. ered with reinforced concrete slabs air inches in thick-ness. The conduit is lined with concrete from eight to twelve tuches in thickness. South of Hatwee v

the size and

shape of the aqueduct vary considerably, and they were determined by the topography of the country and the char-acter of the soil. The average size is twelve feet wide and ten feet deep.

The Tunnels. The enermous amount of tunnel work, the great length of the tupnels and the rapidity with which they were drive n. constitute one of the mo notable features of the aqueduct. All told, there are tunnels on the line, varyfrom 100 feet to the great Elizabeth tun nel, 20,870 feet, or over five miles, long. All world records for tunnel construction were broken in this tunnel. The Board of Con-sulting Engineers was that one year's time would be required for preparation. four years for actual con-\$1,013,000 to cover the cost. Work was commenced simultaneously at both ends of the tunnel, October 5th, 1907. and 250 men were employed night and day in boring the mountain. An average rate of 11 inches per hour was made throughout, was completed 1911, to a

years and 7.8 months and at

months and at a cost of \$500,000 less than the optimate, it is the exceed longest water turned in the United States. This total length of tannels on the signature is \$10,000 miles, at which 42,000 miles at on the meth squeduct, and \$400 miles on the power system.

The Shaevrett Systems.

leading to this reservoir is 500,000,000 gallons per day -about twice the capacity of the aquednot below that point. It is made so large for the purpose of carrying the excess flow during the melting season and accumulating a large reserve. The reservoir, which occupies a former channel of the Owens River, is now a large a notant challent of the Owens haver, is now a large lake seven miles long, with an area of 15 square miles, and a storage capacity so large that in case of emerg-ency it would amply supply the city of Los Angeles for three years. The Fairmout reservoir is 127 miles south

feet above the city. They will impound the water just below the outlet of the aqueduct, and regulate the distribution. These two reservoirs mark the end of the Los Angeles aqueduct proper At the recent bond elec-tion, held April 15th, 1913, the city voted \$1.500,000 additional bonds, to construct a trunk line from these reservoirs, 28 miles to the city limits, where it will connect with the city water mains Crossing the Valleys.

# Hugh Lincoln Cooper

## The Man Who Built the Keokuk Dam Across the Mississippi

By Will P. Green

PERREVERANCE is the keynote of the success of liquh Lincoln Cooper, chief engineer of the £27, 500,000 power development dam across the Missistoph River at Kookuk, Iown Cooper persisted in pushing the Keskuk project to completion when men of less determination might have abundanced their plans, with the result that to-day the concrete monolith stretching from the Illindus's to the lows shore stands not only as a monument to engineering skill, but also to the tennelous spirit of American engineers.

Mr Cooper states that fifty-eight expitallists showed him out of their offices before one man could be found with the confidence to hivest his money at Keokuk. Many of them kinex that the necessary power was in the Misod-suph, and more of them were acqualated with Cooper's standing us an eighteer. Investigation, on the other hand, and opinions from eminent engineers, were to the effect that conditions at Keokuk were possular to the extent that a trainfus wheel never had been built to meet them. "That's all right," was Cooper's answer. "Then we'll build one outereleves." And he

"Then we'll build one ourselves." And he did, designing a turbine wheel specially suffed to the conditions, and when the plant is entirely completed, thirty of these wheels will be developing the maximum power of which the Keckuk dum is enjoine.

When Couper flowlly found money to finance, the Newlan Project, It was not American capital. Singlishmen, in fact, seemed to have the greatest conflictness in the ability of the American engineer. They had seen blin drive a runnel under the center of Horseshoe Palls at Nispara, and in addition to that he had built a number of great water power plants in foreign countries, unung then Brazil, Mexico and Januslea, and one at McKall's Ferry on the Susquedminn. The total amount of capital showed that sixt-five per cent of it came from England, Prince, Canada and Beighm, and thirty-free per cent from the United States

In constructing the Keckuk dam tooper was confronted with some stupendom problems; an instance of which was the lattle with the lee during the spring of 1912. From the beginning of the construction period it was evident that the worst conditions would be met by the lower confrontment with the constantly in mind when he dayned the theory of the constantly in mind when he designed the cofferbain, and the methods of meeting the attacks were thought out far in advance of their coming.

The lee in the Misobodiph usually breaks up in March or April, and moves down the river in large calcs, often 400 or 500 feet square. As it floats down stream, the contact with watmer water and numerous obstructions usually breaks it up into a mass of smaller pieces. The momentum and pressure of thousands of tors of see thus possing down a river

It is difficult for the layman to comprehend. In the spring of 1912 the construction had so far progressed that there was a clear space

between the dum as it had been completed from the litticists side and the lower cofferdam of about 450 free! The openings of the bidge pleas were closed so that all of the ice was faced to pass our through the single opening between the end of the dum and the cofferdam.

The lowe coffeeding consisted of a stransverse line of cribs at the north and of the power house site, extending our about 1.200 teet into the tiver. The cribs had on their outside force i line of vertical plank sheeting, and outside of this a clay emianisment. The apstream side of the embodiance that been covered over which loses racte to dividite the searching action of the current. At one corner of the cofferding a wing of eribowch was built to throw the current out neutre the center of the river. In preparation for resisting the fee action it was expected that be doubted down the river would strike the apstream tog of the cofferding, being through our up on the inclined surface of the rock protected fill and forming in itself a burrier to defect the tee following out bird the middle of the river.

The fee was from two to three feet in thickness, and so into was the spring that Mr. Coper thermed that a large quantity of ice probably would be released at one time. In order to afford additional protection, additional cribs were built, armored with loder plate. Part of the crib construction was built four feet higher and loaded diews with rock.

and loaded down with rock.

The first break in the ice lodged quite a field of it in the opening between the Iowa coffordam and the

Illinois coferdam. Men were on duty day and night to patrol the orderdam and to watch for developments. It was 2 colock on the afternoon of March 23rd when the see above the cofferdam resulty broke and started downstream. As had been expected, the advance flows the desired and the contract of the cofferdam, finally piling back on the to-following and forming a great hand. Orest quantities then began to wedge through the opening in the river. The cuttre defensive conservation withrough the opening to the contract of the started of the starte

struction withstood the attack perfectly.

But a gorge soon formed several miles down the river, and the stage of water at Keokuk went up to a point higher than the cofferdams ever had been called upon to withstand. The gorge broke, and the river foil. Again a gorge formed, and the river rose to seventeen foet. The cufferdam was designed for a twelve-foot stage; but the filling had been carried up so that it really was good for sixteen feet. Cooper ordered the cofferdam raised higher still, and night and day steam shovels and a force of men kept pace with the rise of

Who designed, financed and built the great Kookuk dam across the Mississippi,

the river. For two weeks a flood stage ensued. Design points appeared amount without warning, and prompt action was always necessary. When the water was at its lighest, windstorms threatened to undo all prompt action was always necessary. When the water as the flow of the stage of the properties of the stage of the

High L. Cooper was born in Houston County, Minnesota, and he was still in his forties when he built the
Keckuk power dam. As a boy he grew up with water
wheels. His schooling was limited, and observation
made up the greater part of his education. His father
was a water-wheel owner and builder, and the boy
carly erinced a keen uirerest in the engineering idee of
the work. His first real work was with a bridge construction, company, but Cooper always had hydraulie
engineering in mind, although his initial work as an
engineer in business for himself was in the construction
of a bridge in Washington.

Later he went to foreign fields. Cooper has a great

respect for foreign labor, and even now he stops with interest to watch a Slav or Balkan on the 50b. The countries in which he worked have already been mentioned. He returned to America to build at Niagara, and later on in the Mississippi.

After completing the project at Kookul, he desided to take a six months' vestion in Burope, and there he is at the present time. This master engineer shrinks from publicity. When the great Kookuk dan was dedicated, he was among the missing. Purposely he wanted to a wrist the motoriet; mentioned with it. His personality in the state of the motoriet of the personal with the state of the motoriet of the motoriet with it. His personality is not the state of th

#### Treating Deafness by Electricity

THE partial deafness connected with inflammations of the middle car is considered incurable in many cases, and patients must be content with get-

cases, and patients must be content with getting rid of the original affection (suppuration of the middle ear, etc.). As regards otoscierosis, both the affection and the concomitant deafness may be said to be incursible.

Dr. Hamm, an ear specialist of Brunswick, Germany, has devised a new method for healing partial deafness in such cases, especially in young people, by electric heat effects (diathermy) on the tissues of the ear, by means of a special device designed by Prof. Feukert of the Brunswick Technical Haft School.

The ototherm, as the new apparatus is called, comprises two disk electrodes—one of hich le fixed and the other rotatable—con-ected up to a circuit into which a capacity and a self-induction coil are inserted. The two electrodes are arranged in front of each other, at a distance of a fraction of a milliinterval being taken up by a layer of oil or alcohol, renewed by a continuous sup-ply of liquid. The movable electrode is set rotating by a small electric motor. The two electrodes are surrounded with a sheet metal cover, preventing any projection of oil (or alcohol). A continuous or alternating curr tension connected up to the two electrodes, of course, produces in the oscillatory circuit alternating currents of very high frequency, the number of cycles of which is controlled by loosing a proper capacity and self-inducti The self-induction coil is coupled to another of a tension depending on the number of spires of this coil are produced. The effect of mutual induction between the two colls is controlled by varying their degree of coupling, i. e., by inserting them to a variable distance into each other. The terminals of the second coil are connected up with the electrodes, one of which (a light brass electrode coated with deer skin moistened with warm water) is, before

starting the apparatus, cuttlously introduced as far an possible into the external part of the ear to be treated. The heat generated by the high frequency currents is controlled in as simple a manner as possible by shifting the cells, and is increased as far as the patient is able to stand it. The consumption of energy of the apparatus is extremely low; the ototherm is connected to any scedigi like, an electric issue in the varies from one person to the other, being even different for the left and right ears, respectively. The duration of a sitting is for each ear five to ten minutes, and the number of siftings one to three per week. Some cases are cured in a fortnight by four to five stitings, whereas others require a treatment leasting several mouths. Any cases' susceptible of being cured by this method show already after the first sitting a notable innorevenent.

In view of the satisfactory results obtained in a number of cases. Dr. Hamm does not hesitate to declare that dothermy is a therapeutical process, silowing chronical affections of the tympanum and chronical inflammations of the middle ser (oitile) to be cured. It affords a means of combating the partial deafness consecutive on supportation of the satisfies ex, even in case this requires an extensive suspical operation. Ottobercy staple or contribud (with firetigate) traitment, would also seem at least to improve certain cases of otostiss-

# Plager Print Detection by Chemical Moun

"I HE downess method of making finger prints clearly a 'taible is to optimize taitum powder, or a luminium powder or a preparation of chaik and maccury over the suspected spot, and then brush the spot slightly with soft examels harb treath, when the lines of the finger tip show up in white. The writer has recently discovered another way to secure these impressions in black or brown black, by chemical means. If a finger print is made upon a plece of hard-surface paper, or an impression of the thumb or both, a very fine powder of dried accetate of lead may be excitated over the places where these impressions have been made and then the superfluous powder, after which the spot should be submitted to the fumes of a spublic of ammonium. The markings will then develop immediately into bold clear lines of a brown black color, due to the formation of sulphide of ammonium.

If sheety powdered dry obloride of allver be used instead of acctate of lead, the sulplus powder being removed in the same way by tapping the paper, it will be found that on exposing the paper to the action of light (eunlight if possible) the finger prints will develop perfectly. Of course from these developed impressions a negative may be made and prints made therefrom, either by direct printing, or by development. It has been found by testing that if the paper em-

It has been found by testing that if the paper employed for this class of work is coated with plain colcidion so as to make it non-absorbent the impressions
become very brillian, and can be fixed by floating the
paper back down upon a mixture of suiphuric ether
and alcohol in equal parts, the penetration of which
softens the colicidion entrace, causing the sulphide of
lead, or reduced silver chloride to athere. A finger
print upon a glass tumbler, a glass pane, or upon office
brass work can be brought out distinctly in black by
placing a place of white paper in the tumbler in cylinder form. A negative can be readily made from the impression. Accetate of lead appears to give blacker impressions with the sulphide of aumonium. The access
panying photographs abow flanger prints readed visible
by sulphide of lead and by chloride of silver developed
by light.

#### How Telegrams are Sent in China By R. E. Chambers

THE Chinese written language has several hundred thousand different characters. None of these can be spield so as to indicate accurately how they are pronounced. Besides there are hundreds of ways of pronouncing such character, as there are hundreds of spoken dislacts in China, sithough the book language is the same throughout the country. How is it possible to send a telegram in such a country and in such a language? The difficulties have been overcome, and it is really less trouble, and less expensive to send a message in Chinese thap in English.

The telegram published horsewith will help to make

The telegram published herewith will help to make the matter pisin. There is in every Chinese telegraph office a special dictionary, or catalogue, or code book, whatever you may choose to call it, in which the characters are numbered from one on up. A total number of 9,000 may be catalogued under the present system.

Dinese telegram showing the number cole.

Finger prints rendered visible by sulphide of lead.

Finger prints developed by light after treatment with chloride of silver.

A certain number of blank spaces have been reserved to add special characters from time to time. The sender of the telegram simply writes his message in the usual way. The operatio will probably know the numbers of most of the characters. If not be can readily find them in the catalogue. For each character he sends a few flower signais, e. g., 6013, 6013, 6014, which represent the characters "Yuan Shi Kai," the name of His Excellency, the president of China, who sent the telegram here reproduced. It will at once appear that only ten different signais are needed for telegraphing 9000 different characters in Chinese. By splitting up an unusual character into its common parts it may be easily sent. Private codes are readily prepared with

Fireman's smoke beliet with intake near the floor.

this system. Already the chief cities of the country, and many small places have telegraph offices It hoped that under the republican form of government the whole sevrice will be extended, improved and made increases to mention that the telegram published berewith is an appreciative reply of President Vian to a telegram which the writer as president of the China Baptist Conference sent to him upon the occasion of the call for special prayer for China. In addition to the ordinary wire service, China now has several powerful wireless stations, and arrangements are being made to cover the country with them.

#### Transforming a Schooner into a Grain Lighter

S HORTLY after the directors of the port of Boston succeeded in getting the Hamburg-American Line to shift a part of its lustiness to Boston, it was discovered that there was no grain lighter in the harbor with sufficient elevation to load the new liners.

aufficient elevation to load the new liners.
In this emergency the achoner "Bilen M. Golder"
was secured and practically stripped. She is 103 feet
long overall, by 55-500 bound of 650 tonnage. Rine
with a capacity of 22,000 bushels were built in the buil,
An engine was then installed in the sterm and goard to
a shaft running forward to a point about haif way to
the bow where a rope shave trunsmitted power to the
head shaft of the twe main 20-inch bucket elevators.
To feet showe the deck.

At two points between the engine and the rope drive,

power is taken off through gentred to one point to drive two cross shafts provided with rigorebands which serve to move the lighter backward or forward to a better to move the lighter backward or forward to a better to shaft which in turn operates a secondary shaft running shaft which in turn operates a secondary shaft running the lengthwise of the schooler. The latter serves the end as a head shaft for the two 16-linch distributing elevators.

The lighter is loaded to its full capacity at a grain elevator and rowed alongoide of the litter to be loaded. The capacity of the lighter is equal to a day's work for the main elevators which draw from the bins amidships, and the smaller distributing elevators for and aft deliver grain to the main bins at a rate which insures all the hoppers' emptying simulationnisty.

#### Smoke Helmets for Firemen By J. R. Schmidt

THE helmets pictured herewith enable a threman to remain in a smoke filled room for an Indelhilte length of time without resorting to the new of oxygen tanks to sustain life. They have recently been adopted by the fire department of Cleveland. The new device consists of a canvas bood, somewhat similar in appearance to a diver's belinct, with index squares admitting light. This first closely over the head and shoulders. From it trails a hose which reaches down to the floor, through which are is carried to the warer

As bested snoke, fines, etc., have a tendency to rise, there is, ordinarily, more free oxygen in the snoky here to conclose to the floor. In walking around in a snokes taken from the hearter the behands breathers the air taken from the hearter of the behands the taken from the floor by the traditing hose. Air vulves in the top of the helmest affect scene for the exhalted air so that a freely supply is always received from the exhalted floor. To prevent the hone from collapsing a spiraling runs fits entire length and a heavy end keeps the hose always mear the floor. Experiments have shown that a person can remain in a snoke haden room for vantages of this helmet are that it dispenses with heavy studyed to oxygen takes and may be worn by man or woman of any size, to whom it may be adjusted in less than a minute's time.

#### The French Prohibition of Inflammable Celluloid Films

A FTER December 1st the ordinary celluloid moving picture may not be used in France Instead an uninthammalie film must be used Thomas A. Edison issued the following statement when informed of the new French law:

"There is no possible material known that takes the place of the present collision film. In this country the longurance companies have been so strict that everything pertaining to the film and machine is tnessed in tron and assesses so that the clume of a fire is reduced almost to immunity. Out of 13,000 moving picture theaters we searcely ever hear of a fire, although the theaters are ranning sineset continuously. The muomit of fins stored in the treperod booth at any one time is so small that it is difficult to finastine any danger to the theater even if the whole unmuni should have up. A properly designed machine provides fumunity aside from the fireword footh."

Schooner converted into a grain lighter.

# What Are the Ten Greatest Inventions of Our Time?

## The Second Prize Article in the Scientific American's Invention Contest

By "Altair" (George M. Dowe, Washington, D. C.)

Wilen one considers the vast number of inventions of our time, and endeavors to compare them as to their relative importance, there is suggested to the mind, as a basis of comparison, the inventions of other times, and also the question of the origin of inventions generally

may perhaps be accustomed to think that all inventions are of comparatively recent origin, but a glance at man even in the savage state, will indicate that such is not the case.

in man's earliest struggles for the means of sub sistence, he was obliged to invent some means to sid his natural powers in procuring his food, his shelter, and his clothing, or else lose in the race with other animals contemporary with lim, and many of which were more powerfut than he This conflict arose from the beginning. Man could not fly, like the birds be sought for food, nor burrow like the bear, whose skin he coveted for a closk. His problem was to invent missiles that could move faster than the objects of their pursuit, and to create tools for digging and compel burrowing animals to quit their dens. As the modern inventor is ever seeking to improve the instruments he uses, to adapt them more perfectly to his needs, so the genius of early man was engaged in adding speed to his feet, momentum to his fists, and strength to his

ne aspect then the history of humanity may be viewed as the history of the development of man's in-ventive faculty, and thus viewed man has been an inventor from the earliest times and inventions have been made in respanse to needs; in the desire to bring about inter results by less expenditure of effort.

The most impelling of the needs which have stimu-

lated the exercise of the inventive faculty, have arisen from the desire for food, the desire for shelter from the elements and the desire for rest and bodily comfort; and while few and simple in savage times, and won numerous in modern days, yet they may referred back to the same stimuli which impelled the savage to invent the flint tipped arrow or the fire stick.

As man emerged from the savage state and became ore and more civilized, to these primary needs were added others, the most important of which was the need for means of communication as distinguished from transportation, the need for means of transportation having arison incidentally with the production of food itself. This need for means of communication was early supplied by the invention of writing, and after the lapse of centuries, it was further supplied by the invention of printing from movable type

From the earliest civilized times then, it is clear that the most important of muo's activities have been directed to the production of food and the materials for cloth ing and shelter; to the transportation of himself and his products from one place to another; and to means

The importance of an invention therefore, may be judged, by considering whether it has sided in production, in transportation, or in communication, for unless man can procure his prime necessities and trans-port them, without using up all his strength and all his time, he would have no opportunity to develop the fine arts, literature or science, and the civilization of our own time would not be possible. Based on the foregoing considerations, the ten in-ventions selected as of greatest importance are as

Electrical Fluitton of Atmospheric Nitrogen Preservation of Sugar Producing Plants High Speed Steel Tungsten Fliament.	Aid to Production
Aeroplane. Steam Turbine Internal Combustion Motor Vehicle Pneumatic Tire.	Aid tn Transportation.
Wireless.	Aid in

Electrical Fixation of Atmospheric Nitrogen.
For our food we are dependent primarily on the seel A most important element in the growth of plant life as is well known, is nitrogen, and it is an important problem, how to supply this ingredient artificially and cheaply so as to preserve soil fertility. Of comparatively recent discovery are the nitrifying organisms which have the ability to take nitrogen from the air, but owing to the great number of varieties of these or-

Mr. George M. Dowe, the author of the essay published on this page, is the winner of the second prize, value one hundred dollars, in the contest anred in our tasse July 5th, 1918.

nounced in our tesse July 18th, 1915.
Mr. Dovo very systematically classes all common human activities as relating either to production, transportation or communication, and then considers in turn the principal contributions of recent inention to each of these fields.

The atmospheric firstion of nitrogen on an in

The atmospheric fleation of milrogen on an in-dustrial scale abone signs even at the precent day of rivaling in certain the production of nitrogen compounds from other, longer established, but less incabausible sources. There can be little doubt that Mr. Dove is right in placing the development of this industry at the head of his list of inventions relating to Production.

Aids to Transportation show a particularly bril int record of new developments during the last thems record by the descriptions as which is also the themselves of the description of the department, though only the future can show just what the aeroplane is yet destined to achieve

And as to aids in communication the lives that have even now been saved by scircless telegraphy, who can doubt that in this field the inventions of Hertz, Marconi and the other pioneers of electromagnetic wave signalling stand first!-

ganisms, it has not been found entirely satisfactory to use them for increasing the supply of nitrogen in the soil, so that fertilizer in the form of Chill saitpeter is used to an enormous extent.

The question that naturally arises, is the quantity of sterial availab

Based on careful calculations, Mr. Edstrom, in a paper read before the American Electro-Ct ciety, estimates that the mines in Chili will be ex-hausted about the year 1940.

The discovery, therefore, of a process commercially

The discovery, therefore, of a process commercially practical, by which the exhaustiess altrogen of the atmosphere may be imprisoned and used to support light it is, is to be welcomed as a great cphierment. It has long been known that the electric spark, passed in air, produced a combination of the oxyge and nitrogen, giving an oxide of nitrogen. The problem was to do this on a commercial short. do this on a commercial scale.

Through the efforts of Bradley and Lovejoy, and Birkeland and Eyde, apparatus have been perfected by intectand and xyue, apparatus nave occur percepted by which the electric current is used to such advantage that pure nitric acid can now be produced in sufficient quantities to make the process a commercial success From the acid, fertilizers in the form of nitrates are

made by well known means

Preservation of Sugar Producing Plants. The value of sugar as a food is so well recognized

adays that no argument to this end is needed. In the making of sugar, however, it has been no in the making or sugar, nowever, it has need necessary, under processes until recently known, to get the sugar plant to the presses while fresh, and consequently the entire product must be handled during the harvest cason. This makes it necessary to have the refining plant of sufficient capacity to handle the product in a

Mr George W. McMullen of Chicago has discovered a process of preserving the cane or beets for a long time without losing any of the valuable sugar content.

in the case of beets, for example, they are reduced to a desiccated and finely comminuted condition before the sugar is extracted. The raw material thus treated can be shipped to refinerles having the most approved

apparatus, and the refining can be done at leisure.

The carrying into effect of this process means a a great increase in the supply of food in the form of sugar and therefore places the invention among those of the greatest importance to manking.

High Speed Steel.

The discovery of the method of tempering so-called tungsten steel by which tools made of it would cut at or near red heat, and not lose their temper, can be called nothing short of marvelons.

To make a not for cutting, with a keen edge that would hold, has been so important to man, that in all stages of his history, from the age of fint to the present day, he is found endeavoring to improve its cutting

mpering was very early discovered, certainly before the Christian era, but the practice from the sarties

times has remained substantially the same. Mesers Taylor and White discovered their process

According to all tradition, a steel must not be heated beyond a red heat when being tempered. What could be ver that by more astonishing therefore, than to disc heating tungsten steel to almost a meiting temperature and then cooling, a hardness was produced that was heretofore unknown and that tools so made were able to cut at such a speed that they became almost red hot without losing either their temper or their cutting

ut these are the properties of this new ki and its production has doubled at least the cutting capacity of tools made of it. When one can improve a tool or a machine so that its efficiency is increased five per cent it is considered noteworthy, but when the gain is one hundred per cent, the achievement is nothing short of revolutionary.

Tungsten Filament Lamp.
The production of fire by artificial means has been stly regarded as the greatest invention in the history of the human race. From the illumination of a fire to the Masda lamp of to-day is a great triumph, but the step from any one to another and better of the various illuminants which have marked man's progress no greater than has almost yesterday been me the step from the carbon filament to the tungsten file.

The very great importance of the new lamp can be preclated when it is remembered that the tungsten is remembered that the tung lamp gives the same illumination for a little more than one third of the energy required for the carbon lamp.

To Messrs. Just and Hanaman of Austria is due

the credit for the discovery of the process by which a tungsten filament could be produced which was coherent erent and homogeneous It remained for Dr. Coolidge how-ever to unfold a process by which tungsten could be ssfully drawn jute a wire and by which the perfected lamp of to-day is made possible.

Aeroplane.

It has been suggested in the early part of this paper, that transportation was incidental to production. In fact, it has sometimes preceded it, for before the man woods could catch his game he had to transport himself to the place where the game could be

The means of transportation used has varied with the surroundings. In the frozen lands, the sledge and snow shoes are the aids in the briered wood, leggings as well as shoes were worn. Each of these device increased speed and saved time.

It is in the race with time that man has made re alde progress. Fast bosts and fast trains now take him from place to place and the time devoted to the procuring of the prime necessities, is being ever reduced. To these achievements by land and sea, has now been added another, the conquest of the air, thus widening still further the field of available modes of transports tion.

To Laugley and to the Wright brothers must be awarded the chief honors in the attainment of mechanical flight. Langley furnished an immense amount of data upon which the Wrights worked, while they found out what was necessary for stable flight.

Steam Turbine.

The steam turbine marks a new era in the utilization of steam as a prime mover. Its introduction has brought about a revolution in the design of high speed machinery. It contributes to production and also to transportation; to production through its application to the generation of selectricity; to transportation through its application to the swiftest steamers.

Mr. Parsons, to whom the greatest credit belongs for the introduction of the turbine, has performed a service which surpasses in importance all improvements in the utilisation of steam since the days of Watt.

Internal Combustion Motor Vehicle.
The wonderful clasticity which the internal c

tion motor vehicle has given to transportation gives it a place among the greatest modern invention this is not its only field of importance. It It has been applied in production also, and it is in this field that its use is beginning to be more and more approchated. fit use is businning to be more and more appreciated. Not only in the large tractor by which several farrows, say plowed, hardward and seeded at one operation, but to the small implement for first use in the wooderful adaptability of this form of "whiche shows." While numerous laysuators have contributed to the development of various spirits suspirile prior the gentlement while to the contribution of the contribution of the development of various spirits suspirile prior the gentlement while of to day, the issuate strong, promiserably connected

#### Electrical S

RIGALING Devices,
RIGALING DEVICE FOR ENTIMATING
DISTARACER.—J. U. SHITH. 2320 Ward St.,
Berksley, Ca. I. The invention comprehands the
use at the transmitting station of an oscillator
for Sertian ways, or their equivalent, which
trawel directly through the either at the speed
soler water for propagating aconstic disturbances, the receiving station comprehending a
wave detector responsive to the oscillator, and
also including a sound-controlled triephonic
transmitter, this and the wave detector being
arranged to control currents passing through
a templone receiver.

CULTIVATURE—J. B. Thereical investion of C. Vascu, Randford, Inn. There is the rest of investion that the control of the contr

CULTIVATOR.—V. LAURR, Stillwater, Okia The injention here is to provide a wheeled device wherein the wheele are so connected for the cultivator that the driver may simultaneous-

CULTIVATOR

ly swing the wheels with respect to the culti-vator to change the direction of anyocuent of the cultivator, and may hold the said wheels at any dealred angle with respect to the culti-vator.

Of General Interest,

RLUF PRINT FRAME — J A HIBSTERSO,
215 N 20th N., Manhattan, N Y, N Y, and
J. W. Harvings, N Y, N Y The primary object of this invention is to so manute a plural
ity of binding strips upon the main frame
and to operatively connect them as to make
them all operable annutraneously by a single
morement of an actualing member
(CONCA) BROWN CONNECTION (CONCA)

movement of an actualing memory of PMLLs, Cottagebill, Fis. In the present patent the invention has reference to concrete construction, and it has for its object the prison of modification and the set of the object window frames, and means by which the sash pulsays and weights many be disposed in the concrete frame

weights may be disposed in the concrete traine BOTTLE CLORURE.—R. E. RESDIAM, 1325 80. 9th St., Terre liaute, and The invention provides a closure which is more annitary than the ordinary peateboard disk. This is due to the provision of a cloth strip which forms an

MOTTLE CLOSURE.

auxiliary rissure member and prevents dist and dust from entering the bottle while the main closure nember is being removed. It also provides a device having a closure of the type described which may be readily taken off or applied to the bottle.

anxiliary rissors member and prevents diet and distribution microling the Dritt while the main closure member is being removed. It also profess a derive haring a closure of the type species at the opposite and and clamping means profess a derive haring a closure of the type short at the opposite end and clamping means observed which may be readily taken of ar that his culture, having only one interested which may be practice. On the state of the principal objects of this threating of the third profess and the profess at the state of the principal objects of this threating of the U-frame may be made. See to provide a fill having a thundel like of the threating the profess of the U-frame may be made.

NUTL LOCK.—W. B. MAYWALL M. W. This investion health and the provides of the U-frame may be made.

seri stonission of best to the metal frame and roriciting parts of the platforms named; to provide a plurality of platforms stranged in conjudicion with the above membrased platforms to confine the heat within certain areas; to profile for preventing postering of air; to adopte the providing representation of an and to provide means for resisting east of a sagre higher than that required for the turning of material being handled.

DEVELOPING TANK.—J. H. DROSSER, DEURYLE, ATE. The aim of the investor is a series of the provided to the turning of the series of the series

DEVELOPING TANK.

during the operation, together with a pinral ity of anxiliary tanks for containing the var-ous fluids, supported in the main tank an uneans in connection with the main tank to holding one of the auxiliary tanks of the mai-tank.

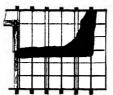

PENCIL—J. A. Walls, 39 U S Fidelity Bidg., Balttmore, Md The invention is of ass more particularly for pencils for writing orna-mentagogins and the like. The essential object

ORNAMENTAL SIGN WRITING PENCIL

is the provision of a pencil core so formed that in writing a succession of signs a rthbon-like appearance will be given, which will show a progressive development of atriated form, whereby an erasure or interpolation may be endity detected.

FRERINGOF PARTITION.—G. H. GEBAR ERDTR. 1346 Roone Ave, Bronx, New York N. Y. in order to accomplish the purpose or this invention use is made of freprot boards of planter or the like, set up on edge and

FIREPROOF PARTITION.

abutting at their edges, vertical bars attached to the finor and ceiling of the huliding and in contact with the opposite faces of the set-up boards, and longitudinal rods held on the said larm adjacent the faces of the said set-up

Hardware and Tools,
MICROMETER CALIPERS.—J. H. MOLLER,
1519 E. 24th Ave., Oakiand, Cal. To obvicts
everal difficulties Mr. Multer has invested a
caliper which refers more particularly in the
class comprisings.— W.which refers more particularly suprising a U-frame, having a

removal when desired, the construction, how-ever, being such that the nut is positively decked preventing accidental or unintentional opening thereof.

Machines and Wechanical Devices.

CANINTER BUPPORT — A. Il Cunzar, 24

Hamilton Place, Tarrytowu, N. Y. This in
vention relates to a convenient unchanism for
supporting a canister designed to boid tea,
four or any commodity; and it sain invitudes
means for monsting the support upon various
fatures and for supporting aboves or the like
by the aid of the canister support

by the sid of the casister support
VALVE GRAR—C. B. PILIN, 408 E. 6th
St. McCook, Neb. The invention provides
means for readily changing the lead of valve
gears of the Waischnert type The combination lever is provided with a sint, in which
alidea a block connected with the valve atm,
so that this lever may be raised by a link connected with an operating device in the eagine
ch for changing the lead of the engine.

DATING MACHINE.—E E. Gascoav, Cen-tral City, Ksn. Mr. Gregory's invention re-lates to dating machines, particularly for use in banks, real estate and ion offices, and more particularly to an apparatus embodying stamp-

ing wheels for the years, months, and days of the months, having means for advancing a pre-determined number of days through a single actuation of a certain portion of the machine

for this purpose.

ANIMAI. TRAP.—R. P. Vannez, Cristoval.

Canal Zone. This trap is more especially desizemed for capita calculais silve and uninjured,
and arranged to permit ready concealment,
to perofice access to the trap from every direction eacept the bottom to prevent the cacape
of the animal caught, and to protect the caught
animal rought. and to protect the caught
animal from attack by other animals

animal from attack by other animals PHOMETING APPARATUS—II. KAIROUR, 168 Hown Tace, Bronz Herough, N 1, N Y, and C. F. Daver, assen becomed The laws tion provides an apparatus for use as a disadventisement and the like singly or for use in connection with a moving picture machine to permit the user to display the pictures on the acrees while the film in the moving picture machine in changed.

Pertaining to Recreation.

TABLE ARCHERY—J. Mosknow, Ja., 2½,
Gage 8t, Glean Falla, N. Y. This invention
relates to gauve; particularly archery, the
game being characterised by a target losari
of peculiar construction adapted to le used
with a number of darts or arrows, the ocarciton
of the purta being such that the target will retain the darts and arrows when brought lule
organization. These with engagement therewith

cagarement therewith COASTING DEVICE - D GINGGIA, 608 Wa ter St., New York, N Y. This invention refers to pleasure devices and particularly to devices used especially by children in coasting on pave must by the use of wheeis, or upon snow ard lev by musta of runners - The device is improved with respect to the attering uncrhained and adjustability according to the statute of the user.

Norz.—Copies of any of these patents will be furnished by the BCIENTIFIC ANERICAN for ten cents each. Please state the name of the patenties, title of the invention, and date of this paper.

The Jungfrau Railway (Concluded from page 164.) cier in other quarters makes the Jung frau Pass unique among Alpine view

The railway also materially a the journey, on foot, to many points of interest. The summit of the "Monk" or that of the Jungfrau can be reached in and with the aid of the railway the ourney from Interlaken to Zermatt can be accomplished in a day by a very easy be accompassed in a cay by a very easy route. From the Jungfrau Pass a walk of a few hours over the Aletsch glacier brings the tourist to the beautiful Lake Märjelen, whence a mule path leads down to Flesch, in the Rhone valley.

It had been estimated that the railway

would pay if it carried 50,000 passeng It actually carried 84,000 in annually. the year 1911, and in one day, immediate ly after the opening of the Jungfrau Pan station last summer, it carried more than 2,400, of whom more than 1,800 visited the pass. These figures prove the correctness of Guyer-Zeller's assumption that there are a great many persons who long to enjoy the beauty and grandeur of the ofty mountain peaks and glaciers that they could never hope to reach by their own exertions. Hence the building of the Jungfrau railway should be esteemed as a work of civilization that opens to all the wonders of nature which could hitherto be enjoyed only by a few.

Before long the drills and the dynamite

cartride s will again be at work, and the tunnel will be pushed forward to a poin directly beneath the summit of the Jung frau, to which the visitor will be lifted through an elevator shaft, 200 feet deep

#### The Daniel Boone Idea in Education uded from page 861.)

—and work. The construction of build-ings enough to house 150 boys and teach-ers in three months was obviously a task ings enough to h even beyond the resources of the militant Interlaken boys. Regular workmen and contractors, therefore, built several of the dormitories. But the higgest and most picture-sque the boys designed and con structed themselves. The Interlaken build the visible evidences of the school by their very history and type of construction thus symbolized the overmastering purposes of the institution—the gospel of mind and character training through

The new boy at this school, as at all others, is more than likely to be a speci-men representative of the city. Soft in his muscles, a little softer perhaps in his mental processes, absolutely removed thousands of miles from any real human experience, the Interlaken School at first impresses him rather as a punishment than an opportunity. To his horror he learns that not only is he expected to cast aside his fine raiment for rough and ready clothing, but that there are really only three or four servants at the school, and that the boys do nearly all the work. instinct of the average adolescent citizen, under these circumstances, is outright rebellion. He secretly resolves that he will not have anything to do with any such degrading routine. Such a resolution is easy. Though work is the school's ruling idea, such work is purely voluntary. Any oy can enter, confine all his time to the boy can enter, comme all his time to the academic studies, and leave manual labor entirely alone. No one forces him to do anything; if he is that kind of a boy, he can sit day after day and be waited upon can sit day after day and de waited upon by his fellows—most of them, as he pre-sently discovers, as "good," which means as rich as himself. He can eat the food that others have raised; enjoy the steam heat and electric lighting that other boys heat and electric lighting that other boys are preparing for him; pick the flowers that others have planted; and stroll up and down the walks, and spend his even-ings in the log cabins that other boys like

found himself looked up to—has always been something of a leader. But here things are not going so well. The boys treat him pleasantly enough; but they do not regard him as a hero. Now, every real boy cares more for the approval of his own boy world than the approval of his parents or relations or teachers. the boys make heroes of athletes, he will try to become athletic; if scholarly tainments are prised, he will immediately nanifest a great interest in his books At Interlaken the hero is the boy who has charge of the steam plant, the boy who distinguishes himself above all others at construction work, the boy who is the best farmer. The newcomer quickly perceives that the way to distinction lies in developing callous hands. His attitude slowly changes. His white color disappears; out-ing shoes and leggings supplant his once immaculate footgear.

Thus transformed the new boy b difficulty in accommodating himself to the changed régime. In the morning he rises promptly at six o'clock. There are no bells, no whistles, no Chinese gongs, as there are no rules, no terrifying lis "don'ts." There are only four servants— two Japanese cooks and two helpers—to supply the gastronomic needs of nearly two hundred people. The boys do all rest of the kitchen work themselves: they lay the tables, serve the food, clear away and wash the dishes. After breakfast they spend half an hour setting their rooms in order. The school employs no chambermaids and no sweeps; the boys make their own beds, sweep out the room and have everything in good order for in spection at eight o'clock.

The time from eight until twelve-thirty is devoted entirely to the classrooms. Here the namel school exercises hold away. But conventional fashion; they try to relate the old scholarship to the facts of me Formal discipline is lacking. The boys are not assigned to definite They gather in a circle about the teacher, ask and answer questions. A classroom recitation resembles somewhat the conver es somewhat the conversation of well-bred people. In the science s, the boys in the main, manufacture their own apparatus.

After one o'clock the situation entirely changes. Leaving the dining-hall, the boys gravitate toward a large bulletin board. A hundred eager eyes scan the inscriptions; for here the masters have written down the "assignments" for the afternoon. On the board are written the ames of half a dozen boys, who are ex-pected to spend the afternoon plowing with two sixty horse-power tractors. Another contingent learns that it is to devote itself to corn, anoth r to sowing cow peas; still another to laying out gardens for raising vegetables. If it is winter time perhaps the ice is to be harvested; if it is summer the hay is to be cut and made and the corn crop is to be garnered. A large contingent finds its way into the shops, where tables, chairs, desks, and bookshelves are to be made, all for the e school. A year or two ago the boys made two silos, large enough to hold sixty acros of corn. The immutable rule is that of manual labor; and on a farm of eight hundred acres there is plenty of work to keep all the boys usefully em-

Every afterno boys have plenty of time for play. spring they crowd the baseball diamand tennis courts--their enjoyment not decreased by the fact that they have leveled and staked out these playgrounds ieveied and stated out these playgrounds by their own labor. In fail there is soc-er; in winter skating and hockey and playing. Every night there are gatherings around the fireplaces in their own and the masters' rooms-for study, reading, and conversation. There may be lectures and private theetricals. Occasionally some of the boys decorate one of the halls, invite their girl friends out from La Porte and ings in the log cause that other boys in the late gain; triends out From La Force and himself have put up.

For a few days the new boy may hold little was a dance. At either timesy they den himself also C. Then a certain sense of disconfort settles down upon him. In his to the politosphy that respect respectively other school experiences he has plways jetolese are as essential to a full receded.

ary, at \$4,490,000. April 10th, 1910. Lo Angeles voted bonds to the extent of \$3, 500,000 for the purpose of partially de veloping the electrical power of the aque duct, which eminent electrical engineer estimate at 120,000 horse-power peak load. It is not the intention to develop the full amount at this time; but eventually, as the demand for power increases, as it into develop all the power possible will undoubtedly be put in. Mr. Mulholland on one occasion made this public utterand on the subject: "I believe that the peop have in the possible power development from the aqueduct an investment which twenty years hence will turn back into the city treasury the entire \$24,500,000 provided for the construction of the squeduct with interest." This opinion is sustained by the hydraulic and electrical engineers een called upon to examine the

The first electric power plant is 47 miles from Los Angeles, at Clear Water Canyon. The water is led from the mouth of Elizabeth tunnel 935 feet down the preof Englandin unless so feet down the power topfions side of the canyon upon the power producing waterwheels, whence the current will be transmitted to the city over high-tension lines. The plant being erected will produce 37,500 horse-power, and it can be increased at this point by addi-tional construction to a limit of 75,000 horse-power. After leaving the wheels of the first power plant, the water will be carried seven miles along the rim of San Francisquito Canyon and dropped down 512 feet upon the wheels of a second pow-512 feet upon the wheels of a second pow-er plant to be built wheaver the demand for additional electrical energy shall re-quire if. A third power plant to develop a maximum of 10,000 horse-power can be built between the aqueduct outlet and the upper San Fernando reservoir. And still another power plant, capable of producing 8,400 horse-power, can be placed on th main trunk line to the city at Franklin Canyon, in the Santa Monica Mountains. There is considerable work yet to be

and ends of the great aqueduct work, such as building distributing systems for the surplus water for irrigation purposes, and for transmission and distributing sys ns for electrical energy. There is a gorous demand for both water and powwever, and the satisfactory c er, however, and the satisfactory comple-tion of these distributing systems, large in themselves but insignificant in compari-son with the work of building the great Los Angeles aqueduct, will be a matter of

#### What Are the Ten Greatest Inventions of Our Time? (Concluded from name 268.)

with its early progress are pro of Daimler, Ford and Duryea.

Pasumatic Tire.

If fifty years ago I were asked to name the greatest invention of the time, the answer would probably have been the loco-motive. When a hard smooth tramway was first conceived, the beginning of the future greatness of the locomotive had been made.

what the track has done for the loco-motive, the pneumatic tire has done for the vehicle not confined to tracks. Here the advantages of the track must be pro duced in the tire. Shock must be reduced to a minimum and sufficient traction must be provided. Both these factors the pueube provided. Both these ractors the pneumatic tire possesses to a high degree. By its use, the automobile of to-day is possible, with its high speed and smooth riding qualities, and by its use also the amount of power to pull a given load is much reduced, thereby aiding man in the transportation of himself and his goods.

To the efforts primarily of Bartlett, the inventor of the cliucher tire, and of Dun-lop, the inventor of the wired-on tire, are due the practical results in tire construc-

#### Wireless.

The development of the means of comnunication from one place to another by signals of some kind makes a remarkable chanter in the history of invention. chapter in the instory of invention. Water early man went with a few of his com-panions to a distant place for any pur-lose, it was often of great importance for e left behind to know how their comnanions fared.

cation has always been felt, and it has been supplied in different stages of prog-ress by the fire kindled on lofty hilltops, by the semaphore, by the electric tele-graph, by the telephone, and finally by means of the Hertzian waves. Each and all of these methods of communication have been devised to meet the needs of erce primarily, but incidentally they have contributed to social intercourse.

While the development of wireless ha been of gradual growth, and a number of inventors have been at work on its prob lems, to Marconi must be given the credi of making it commercially practical.

## Composing Machines. While the production of fire artificially

is probably the greatest achievement of the human race, yet the discovery of the art of printing certainly stands high among the great inventions of civilised

From the time of Gutenberg, h until recent times, no substantial change in the manner of composing has been made on a scale which could be considered com mercial. Printing has improved from the rude hand press to the giant rotary press of to-day, but the composing end has stood still until the introduction of two brand new types of devices, the Linotype and the M

fore the advent of the had been made to produce a typesetting machine, and while the actual setting could be done, the problem of redistributcould be done, the problem or redistribut-ing the type was still unsolved. The sug-gestion that types be made with different-ly located cuts or notches was not prac-tical, since that necessitated a change at the type foundry.

solved the problem as practically presented, by making a typecasting device a part of the machine, so that composing and casting are now done at the printing office ne being a co

t, 27,000 tons. Gums: Ten 14 inch, twenty-one 5-inch, four submerged 21 inch torpedo tubes

The 27,600-ton "Texas," our first super-dreadnought.

# The First Super-Dreadnought of the U. S. Navy

The "Texas" Armed With Ten 14-inch Guns. Makes Twenty-two Knots

IN 1910 Congress authorized the construction of two battleships which possess special interest because of the fact that they are the first to be armed with the new 14-inch, 45-caliber gun. For many years—to be exact, since the year 1898, when the "Maine" class of battleships made its appearance—the principal weapon mounted on United States battleships has been the 12-inch gun. This piece was 40 cattlers in length as 12-inch gun. This piece was 40 cattors in length as mounted on the "Ohio" and "Georgia" classes comprising eight ships; 45 calibers long as mounted on the fourteen hattleehips of the "Louislaun." "Idabo." "Kansas," "South Carolina," "Delaware" and "Utah" classes, and 50 calibers in length as mounted on the "Arkansas" "Wyoming."

The appearance in the British navy in 1910 of the "Orion," the first so-called super-dreadnought, marked a return in the navies of the world to gans of a heavier a 48-calther 1814-inch gun, and she showed a great advance in gun power over existing ships. The Bureau of Ordnance of our Navy, however, with wise prevision, and organized of our rawy, income, which was previous, had foreseen the probability of a return to heavier guns; and they had built and tested a fine 14-inch rife, 65 calibers in length, with which, after the appearance of the "Grion," it was determined to arm our future battleships. The two ships vessels "Texas" and "Now

plow. The Least rate to be armset with this formination place.

The 1-4-inch gun to 64 feet long, weight 63.2 tons, has a musale velocity of 2,000 feet gen second, and the weight of its shell is 1,400 polents as compared with the shell of the 13-inch, upon which weights 570 pounds. The musale energy of the 1-4-inch shell is 65,607 foot tone. Its extreme range as assessed in the ship is 25,000 parties, and it can penetrain fill highests of Krupp curier at a same of 0,000 parties in significant for the ship is 25,000 parties, and it can penetrain fill highests of Krupp curier at a same of 0,000 parties in significant for the ship is carried as many fill hand to be ship of the contract of the supplement of the contract of the supplement of the ship is a state of the same of the

water line, \$565 feet; beam, 951/4 feet; mean dranght, 23½ feet. Her normal displacement is 27,000 tons as against the 28,000 tons of the "Wyoming." Her full load displacement is 28,067 tons. She is built as a flagship, and has accommodation for 1,070 officers and men. She is protected by a continuous belt of armor 12 inches in maximum thickness, tapering toward the ends, and above this is a belt of slightly less thickness ding to the gun deck, which deck, amidships, is protected by 6 inches of armor. The turrets carry 14

The armament consists of ten 14-inch guns, mounted in pairs in five turrets, two forward, the after one firing over the roof of the forward turret, and three aft ing over the root of the forward turret, and three air of the malimast, disposed as shown in our litustration. For protection against torpedo attack there is a battery of twenty-one 5-inch guns, ten of which are mounted behind 8-buch armor, amidships on the gun deck, the others being disposed, four forward, four aft, two on the superstructure abreast the conning tower, and one mounted on the guadeck satern.

The "Texas" is a decidedly handsome ship. She is The "Texas" is a decidedly handsome ship. Shie is like the "Wyoming" and "Arkanass" in carrying her main dock flush from stem to steric—there being no break from the forecastic deck to the main deck as in the "Delaware" and "Utah." The main deck conse-

the "Delaware" and "Utah." The main deck consequently rises from a freeboard of 18 feet at it o25 feet forward, and the long, unbroken sweep gives a particularly pleasing outboard profile to these ships.

The "Texas" has vertical, triple-expansion, four-cyllader engines driving two propellers. The designed lones-power is 28,100 for a speed of 21 knots. This, on the trial at Rockland, was easily exceeded, the speed secured being 22 knots, with a maximum on one run of 23% knots. In column with all of our greater ships, the "Texas" has a wide raffund of action. See can carry the "Texas" has a wide radius of action. She can curry a maximum of 2,850 tons of coal and 124 tons of oit. The sister ship "New York" is being built at the New York navy yard, where the is rapidly approaching com-pletion. She is practically a duplicate of the "Texas." except as regards her motive power, which wilt cons of Parsons turbines driving four propellers.

A Tire Tread That Can be Reversed.—In patent No. 1,070,460, Clark Francis Fish of Allentown, N. J.,

shows a removable tire tread made thick along its center and thinner toward each edge, where it is adapted to co-operate with fastening devices. When worn on one ade the triad can be reversed, a filling piece being provided for application between the tread and the tire se when the tread has become worn and is reversed

## The Water Supply of Paris

S HOULD the additional water that the city of Paris requires be brought from the Loire Rivet, the expense will be some \$80,000,000. Such water is of good quality, but us the quantity is but 500,000 cubic meters per day, the project has the drawback of being but a temporary one, soon needing to be amended. A much satisfactory plan will be to bring the water from Lake Leman, that is from the Rhone, where it flows out of the take. As the volume is twenty times what would be taken now, there is ample scope for any future would be taken how, there is aimple scope or any trutar-increase, and it will always be possible to take off what is needed for the city's consumption. To bing one mil-tion cuble meters per day to Purks would cost \$120, 000,000 or one half mure than the above project, but the amount of water would be doubled and the supply would be carried out on much better conditions to the purity of the water, it need only be mentioned that Geneva, Lausanne and other places on the lake never suffer from typhold and other epidemics known at Paris, and even then they take the water directly from the lake without the precuntions which would here be used. The excellent quality of the water is recognized by chemists and bacteriologists of all countries

#### Birds As Consumers of Food

I T may not be thought that of all animals, birds are among the largest eaters This means, of course, in proportion to their weight Some birds are known to consume two and one half thues their weight of food in 24 hours. The heron, which has a light weight of 4 pounds in suite of its size, is a striking example. One as lately caught which had just swallowed two trout

11/2 and 2 pounds Wild pigeons are umong the of 11/2 and 2 pounds ost eaters, and they make a most copious repast ever an abundance of food is found. Thus a single pigeon picked up 1,000 grains of wheat in one day.

## The Future of the Dirigible

UR contemporary, The Engineer, of London, whose attitude to inventions of the bolder type is nothing if not conservative, affirms that the ill-fated "'L.2' has ceased to exist because it and its brethren of all types, Zeppelin or otherwise, are me-chanical absurdities designed in defiance of Nature's

So much for the ship of the air; and yet it com So much for the ship of the air; and yet it comes to our mind that some titree quarters of a cettury ago, the ship of the see was subjected to a similar whole-sale condemnation. History for its it radiatory? relates that a certain worthy doctor, in the days when it was proposed to build a steamable to cross the Athuito, proved to an absolute demonstration that such a slip would size under the load of free which it would be cessary to put aboard to carry her from coast to

In all candor we have to confess that, in the earlier years of Zeppelin's experiments and those of Lebaudy and others, we were as skeptical as to the success of the airship as The Engineer was and evidently continues to be; but we are free to admit that in view of the steady creeping up of the speed of the dirigible and the continuous increase in its radius of action, and after seeing the Zeppelins daily traversing the air with ility and with from two to three times the speed of the steamship, we have come to the conn that the dirigible has an assured future and a useful field of work.

Conservatism is a most valuable quality and neces-sary to the orderly development of invention; and there sary to the orderly development of invention; and there is no doubt that the very litelligent analysis made by our contemporary of the various disasters which have happened to former Zeppelius has rendered good service in the development of the art. But when the same tournal states that the obvious lesson of the recent disaster is that "no dirigible halloon has yet been con-structed which fulfilled its function otherwise than by structed which minimal his function directive than by dodging the forces of nature" the least that can be said is that the statement is finity contradicted by the facts. So far from dodging the forces of nature, both the construction and the operation of the dirigible are based, as in all successful inventions, upon a recogni-tion of the laws of nature and a co-operation with them in securing the desired results. The buoyant, engine-propelled, rudder-controlled dirigible covering, at a speed of forty to fifty mlles an hour, the greater part of a nd miles of travel within the twenty-four h is built with the same intelligent recognition of and co-operation with the forces of nature which during the past century has brought the steamship to the stage of perfection represented by an "imperator" or a "Maure-tania." The Zeppelin "I.2" which embodied only about sixteen years of development of the airship, about sixteen years of development of the airsaip, was capable of traveling all day at a speed of 55 miles an hour, and at a cruising speed of 86 miles was cap-able of making a continuous flight of 2,500 miles.

In the face of such facts, and admitting that this stage of development has been reached at the cost of many deplorable failures, we think it is altogether too early to state that the Zeppelin and all its brethren of ever type "are mechanical absurdities design in defiance of Nature's forces.

But to leave generalities and come more closely to our text, we invite the attention of the Engineer to the fact that these airship disasters are entirely preventable. They may be classed under two heads: Those that are due to collisions with the ground or the sheltering langars, and those that have been caused by explosions As regards the former, the Schentire Asset. CAN has always held that the ship of the air should be

maintained in the air, and should never, except in emergency, court the risks of destruction which are entailed in making a landing upon the earth's surface, Many years ago we pointed out that the logical pro-vision for landing would be to erect lofty steel mooring owers (docks, if the name be preferred), to which the towers (docks, if the name be preferred), to which the airship would come up from the leeward, casting her anchor into a suitable circular framework, attached to a turntable which would allow the dirightle to float always to the leeward. Figetimes for gas and fuel would extend to the top of this tower, and by means of flexible connections, the floating dirigible could se-cure such replenishment as was needed. Elevators would carry passengers and crew between the landing

Now under such arrangements the airship would remain affoat until such time as repairs might be neces-sary, when, like the ship of the sea, she would enter drydock. We believe that the function of the shed or hangar should be confined purely to docking work, and that the dirigible should be docked only in calm weather.

that the dirighle should be decked only in calm weather.

As regards the risks of, explosions, we are of the
opinion, as stated in a recent issue, that these are entirely preventable. No far as the engines and their
fuel are concerned, there is no greater risk of explosion in the motive power of an airship than there is in that of an automobile or of a Diesel-engine-driven steamer. The risk comes from the leaking hydrogen and its mix ture in explosive proportions with air; and this as we showed in a recent issue, can be successfully guarded against by providing blowers of sufficient capacity to sweep the escaping gases from within the outer en-

The dirigible has an assured future, at least as an arm of the military service; and the many disasters of the past will no more prevent its inevitable develop-ment, than did the shocking fatalities of the sea which

#### A Cycle in Naval Gun Construction.

The fact that our latest battleship, the "Texas," which has just completed its trials, carries as its principal weapon a 14-inch 63½-ton gun, and the recent launch of the "Quene Elizabeth," which is to mount a 15-inch 90-ton gun as its main armament, coupled with our knowledge of the fact that one lead-ing naval power is just about completing for test a huge piece of 16 inches caliber, reminds those of us who have followed naval construction during the past twenty-five years that naval armament, at least so far as regards the caliber and weight of its guns, has been developing in a circle; and that with respect to size

aversoping in a circle; and that with respect to size and power we have, relatively, reached the position from which we started some three decades ago.

To be convinced of this, let us consider the armament of the leading battleships of those navies of the decade 1880 to 1890 that stood in the front rank. The most verful ships of that period were, strange to say, powerful ships of that period were, strange to say, ships of what most of us have thought was a purely modern type, i a., the battle-cruiser. The Italians, who have ever been noted for blazing the way in pioneer naval work, set affoat two ships of the then unprecedented size of about 16,000 tons, which carried no arm a heavy protected deck and an armored ammunitio tube leading to heavily armored redoubt, and which embodied the remarkable combination of the then high ed of 18 knots and an all-big gun battery of four 17-inch guns, each weighing 105 tons. No one will deny that here was the prototype of our modern Indomitable

At the same time Great Britain possessed heavily rmored battleships carrying each two 110-ton 10-4 inch guns. France was represented by the "Admiral Baudin," which mounted three 14.5-inch guns. Germany had scarcely begun the construction of her mod ern navy, nor had we in the decade from 1840 to 1890. Italy in 1888 discarded her 105-ton guns and armed the "Re Umberto" with four 12.5-inch, 67-ton guns. This piece, like all the earlier guns of the Italian navy, was of British make, and in 1898, the "Royal Sovereign" class was armed with four guns of the same caliber and weight. In 1891 Germany started her battleship fleet with the "Brandenburg" class, which were armed with four 11-inch guns, while the United States brought ont the first three of its battleships, the "Oregon" class, which were armed with four 18-inch, 35-caliber

In the British navy the 13.5 caliber gun con to be the principal weapon until the appearance of the "Majestic" class in 1895, when the caliber was reduced to 12 inches, the ships of that class carrying four 95. to 12 inches, the ships of that class carrying four 35-caliber guns of this caliber. For the next thirteen years, battleships of the British navy were armed ex-clusively with the 12-inch gun, which was increased in length to 40 calibers in 1808, 45 calibers in 180d, and 50 calibbre in 1908.

The French navy adopted a 13.4-inch 42-caliber gun in 1891. In 1893 they armed the "Carnet" and following ships with a 12-inch, 45-caliber piece, and in 1904 they

were still using the lib-hole gan, mounting it upon the "Justice" and sheer ships. Their laisest ships of the "Normandy" class, will carry twice in in-4-sec, gues sounced in three four-you turrets. In the decade 1800 to 1800, the United States Navy Proceed the 12-inch gan, which was mounted in the "Oregon," the "Kennenge" and the "Albesta" classes.

"Kearserge" and the "ARbenna" cames. The 12-then gun mounted first in the "Iowa," 1898, was reintroduced in the "Malne" class, and continued to be the principal weapon of our battleships until the appearance of the "New York" and "Paxas," the length being gradually raised from 40 calibers in the "Maine" class to 45 in the "Connecticut" class and 50 calibers in the "Arkansas" and "Wyoming."

Germany's first ships of the "Brandenburg" class in 1891 carried, as we have seen, four 11-inch 40-caliber guns. The next two classes comprising ten ships, mounted no gun heavier than a 9.4-inch, of which each mounted no gun heavier than a 8.4-lach, of which each ship carried four. In 1804, in the "Deutschland" cleas the Germans returned to the 11-lach gun, and this plees formed the main armanent of the "Nesseau" class of 1808 and the "Heigoland" class of 1908, the calibration of the state of 1808 and the "Heigoland" class of 1908, the calibration of the state of 1808 and 1 it is believed that they will mount a new 15-inch Krupp piece of great power.

tters now stand Great Britain is mounting on st dreadnought a 15-inch 45-caliba-As matters n As matters now stand Great Britain is mounting on her latest dreadnought a 15-inch 45-caliber gun, Ger-many a 15-inch 65-caliber gun, the United States a 14-inch 45-caliber gun, Italy a 15-inch 45-caliber gun, and France a 13.4-inch 45-caliber gun.

Although none of these weapons except por German piece reaches the great weight of the 164 inch 110-ton gun of the "Italia," their striking energy is vastly greater. In flatness of trajectory, in the extent of the danger sone, and in the rapidity of fire they are naurably superior to the great gun of twenty-five

## Sir William Preece

T is a fortunate thing for this world that many of its great men of genius are gifted with a physican that physique that preserves them to a ripe old age, is is not the time and place to discuss the reasons for this observed fact; we mention it only because it is once more brought into prominence by the decease,

at the age of eighty years, of a pioneer of applied science, Sir William Presce.

A man of science may render services to the com-munity in two ways—either by advancing our knowl-edge of and control over the forces of nature, or by directing, in administrative capacity, the work of others in developing scientific and industrial enterprises.

Sir William Preece has ministered to the world's sir whilm rrece has ministered to the world's needs not by one or the other of these two avennes, but by both. As an investigator he was one of the first to turn his attention to the possibility of transmitting electric signals to a distance, without the aid of wires. In 1893, two years previous to Marconi's epoch-making contribution to the art of wireless telegraphy, he su cessfully signaled to a distance of over three miles by electric induction, i. e., without the use of a wire nection between the sending and receiving station e of a wire con-

nection between the sending and receiving station.
To kir William Presee are also due important improvements in the field of multiplex telegraphy by wire
and in railway block signaling. He is said to have
inkroduced the electric bell for domestic services in
England, and to have been the second man in his country to employ electric lighting in his home.
His administrative work was divided into two periods.

His auministrative work was divised into two persons. The first sixteen years were spent in the employ of the Electric Telegraph Company, which was dissolved in 1870, its functions being taken over by the Crown. In consequence of this Six William, then Mr. Presce, entered the Post Office service, in which he remained for twenty-seven years.

Sir William Proces visited the United States several sir william rreces visited the United States several times, bringing over with him some of his innovations in the field of telegraphy. His expressions of regard for our nation and his appreciation of some of those characteristics of which we are justly proud, give him a special place in the memory of the American p

Anatesi Speed Test of Our Destroyers.—In the remot aminsi speed test of the torpedo-best destroyers in commission, the third and fourth groups. Including ten reseals, made prod speed, the "Jouers' exceeding her contexes upon by a versaging 329 on a two hour's run. All of these losts are oil burners. The "Besle" scored 100 piec cost in a smoke test trial, running four hours who absolutely no moke showing at the smokestacks.

The Largest Drydeck.—The Canadian government is about to build on the St. Lawrence, near Levis, Gubes, a drydock which will be the largest in existence. Its dimensions will be as follows: Langth, 1,160 feet; width of entreane, 120 feet; depth of ell as ordinary high water, 40 feet. It will be divided into two sections of 600 and 500 feet. The outer entrease will be closed by a steel rolling oaisson, and the inner entreace by a

Seath Bosten Dyrdeck.—The Atlantic coast of America is shortly to have the advantage of at least two drydools capable of receiving the largest steamer. In addition to the one to be built near Quebee, another of about equal site is to be built as South Boston. The dook is to cost \$3,000,000, and a contract has been entered into by which the International Mercantile Marine, the Cunard, and the Hamburg-American lines will pay \$80,000 a year for twenty years for its use.

American Santiation in South Africa.—Oracle interest is fet by Americans in the visit of Col. Gorgas to South Africa to study conditions at the Consolidated Mines of the Rand at Johannseburg. The mining coffipanies have requested Col. Gorgas and Major Noble, both of the Medical Corps of the United States Army, to make investigations and recommendations regarding the sessitation of this mining district, where about 200,000 men are omnloved.

Rapid Increase in Dreadmoughts.—In view of the fact that only eight years have peaded since Britain laid down her first freedmought, it will surprise many of the naval enthusiants to know that, by the end of this year, the approximate number of dreadmoughts in the world, built or building, will be one hundred and fifty. The rate of increase, as given by an expert writer in the Sph rs, is as follows: One in 1905, nine in 1904, but years of the surprise in 1907, thirty-two in 1908, first-two in 1908, first-two in 1908, first-two in 1909, first two in 1908, first two in 1908, first two in 1908, first-two in 1908, first-two in 1909, first-two in 1909, first-two in 1908, first two in 1908, and 1909, in 1918.

Profits from the New Daal Subway.—Under the new operating contract with the city, the carnings of all the Brooklyn elevated lines and the Center Street loop are pooled. From the gross carnings, the company deuter rentals, taxes, operating expenses, depreciation, and a certain amount paid the company in lieu of the profit it derived from its existing lines when the contract was made with the city. After these deductions, the surplus is devoted to interest and sinking fund charges upon the city's investment. For the first month of operation of the Center Street loop under the contract arrangement, there was a balance in favor of the city of \$22,-\$70.09, which was more than enough to pay the interest on the city's investment and within \$2,814.52 of the sinking fund as well.

British Battisship as a Target.—The battleship "Empress of India," which was built at about the same time as our "Oregon," 'India," and 'India," which was built at about the same time as our "Oregon," 'India," and 'India, 'India,

Strength of Steel Cars.—The report of the Committee on Car Construction, presented at the annual moeting of the Master Car Buildew's Association at Atlantis City, recommends that entiting steel or steel-underframe care which have less than a certain strength must be classified with wooden care, and be subjected to the same relief for combination defents. The standard of strength should be as follows: 1, Area of center sill should be not less than 18 equare hockes. 2. The ratio of streng the should be not less than 18 equare hockes. 2. The ratio of streng the should be not less than 18 equare hockes. 2. The ratio of streng tender of the should be not less than 18 equare hockes. 3. The parts of members of the should be not less than 20,00. 3. The length of entire or depth of the members, pressured in the direction let which buckling might take place. For new cars the area of enters sill should be not less than 26-square families; this insteed of street to end signal not more than 0.00, and the length of center or death oil members or species of members.

#### Reismo

A New Seurce of Guana is the coast of French Somaliland. The guano is shipped to Europe through the port of Jibuti, and is said to be of high quality.

Payer's Expedition to Frans Josef Land, which sailed from France August 10th, has not, according to the Geographische Enterhift, attempted to proceed directly to its objective point, but is to winter at Vardo, Norway, and proceed northward carly next summer.

Prince Galitain, the well-known seismologist, has been appointed director of the National Physical Observatory at St. Petersburg—i.e., director of the meteorological service of the Russian Empire—succeeding Gen. Rykatcheff, retired.

Cooses is the name of a French product manufactured from copra, probably with the addition of small quantities of other substances, which is guining great popularity among Mohammelane and Hindus for use as a butter. Its peculiar resonmendation, as compared with other butter substitutes, is that it contains no trace of long fat or best faultow, and hence does no violence to religious

American Gineses, the market for which is almost containively confined to China and Korea, has been an article of export from this country for more than a century, the price stising, as the wild supply duminabled because of the clearing away of suitable forests, from 40 cents a pound in the early years of its collection to more than 86 a pound for the best qualities during the last eight years. The outlivision of the plant is comparatively recent; it began in an experimental way about 15 years ago, and has more attained such proportions that the output of the cultivated roots almost equals that of the wild. The total exports exceed a value of a million dollars a year.

value of a million dollars a year.

Award of Redgins Prise for Essay "On the Belation of Atmospheric Att to Tuberculosts."—On the recommendation of the Committee on the Award of the Hodgrins Prise of \$1,500 for the best treatise "On the Relation of Atmospheric Air to Tuberculosis," which was offered by the Satishensian Institution in connection with the International Congress on Tuberculosis, badd in Washington in 1908, the Lustitution announces that the prine has been equally divided between Dr. Ouy Hinsdale of Hot Springs, Was, for his paper on "Tuberculosat in Relation to Atmospheric Air," and Dr. S. Adolphus Knopf of New York city, for his treatise "On the Relation of Atmospheric Air," and Dr. S. Adolphus Relation of Atmospheric Air to Tuberculosas.

Pure Atmosphere in Industrial Work Rooms.—It is a favorable sign of our time that there is an increasing tendency among manufacturers to install equipment to raise the saultary standards in the working rooms of factories. Industries in which various forms of dust are seatlered through the atmosphere of the working rooms exparticularly in need of attention in this respect, and the matter is especially grave if the material floating in the open air is of poisonous character. How the problem has been solved in the white lead plant of the National Lead Company was described in the issue of our SUPLEMEARY for July 19th. A special system of wullking and overed hoods protects the workman from the injurious effects of the lead dust which would otherwise contaminate the atmosphere.

Capt. Sedov's Russian North Pelar Expedition, concerning the fate of which much anxiety had been felt since the autumn of 1912, when the least definite news of it was received, is now reported to be safe, for the time being, in the Panerstius Islands, just of the northwest coast of Nova Zembla. This information was brought by several members of the expedition, who were recently compelled by ill-health to return to Russia. The control of the control of

#### Automobile

Folding the Automobile Top Into a Covered Receptacle.—Patentt No 1,071,348 to Ruchard H. Rice of Lynn, Mass, provates an automobile body with a receptacle in rear of the back seat, whose cover can be opened to permit the top of the automobile to be collapsed into the receptacle and then closed to enclose the top.

An Automobile Journey Across Africa, from south to north, has been undertaken by an Englah officer, Lieut. Kelsey, who started from Cape Town August 17th, and hoped to reach Alexandria, Expyl, in 120 days. The first crossing of Africa by automobile from east to west—viz., from German East Africa to German Southwest Africa—was accomplished by a German, Lieut. Gractz, as recorded a few months ago in these columns.

The Peer Man's Automobile.—England is said to have more than a hundred cycle oar factores and it is no casage-ration to predict that America will soon you will beginn the production of the charge automobile. One manufacturer, however, has goon in for the production of a snall cas which is decededly not a cycle car, but a regulation automobile with full width tread, change gear transmission, four cylinder motor and full width seat. This little ear, which will sell for less than \$500, has a 90 inch wheel base and a \$24.8 inch mutor developing about 22 horse-power Under tests on the road the ear has gained a speed of 52 miles per hour.

Petroleum Society Incorporated.—With the object in view of benediting and uniting many unrelated interests that depend to a certain extent upon the production of petroleum, the American Petroleum Society has been organized at Pittaburgh, Pa., and incorporated under the laws of that State. It is intended to make a thorough study of petroleum technology, to certailate the information gausel thereby and to conserve the petroleum resources of America. That much promise for relief from the present fuel situation in the automobile field is hoped for, is shown by the fact that the Society of Automobile Engineers, the American Automobile Engineers, the American Automobile Engineers, the Society of Mechanical Engineers, the Society for Testing Materials, and several others sent delegates to the recent conference.

As Ambulance Rospital—The Queen of Bulgaria, who takes a great interest in the Red Cross service, has had bulk as precial ambulance automobile at a German works, and it was used in the field during the war in the Bulkans. The roomy body of the limousine type is arranged in two compartments, one on each side. On the right hand side are lodged two stretchers one above the other which can be run in by means of rollers through a back door. The other ach has two seats for the aids and is also resched from the back, there being also two side doors. As the said door in the stretcher compariment can only be opened from the outside, it is impossible for patients to leave the ambulance unawares. Ground glass passes give sufficient light while preventing the interior from the outside. Dr Paul Frank, a prominent Berlin insciend official, designed the Dresent ambulance.

French Official Tests of Motor Trucks.—What will rank as the greatest mitor voluels content in the history of motordom has just closed in France, after more than a hundred whiches had been subpeted to an official test by the French War Office, over a period lasting forty days. The trucks began July 1st and ended August 9th. They were participated in by minety-eight manifecturers, most of whom entered more than one undel. The trucks are tractors hading one or more trailers. The former were required to cover 1,085 miles and the latter 1,106 miles in mineton days over a circuitous route, operating on gasoline, benzine or alcohol without changing carburoters. The purchaser of any truck which has successfully mot the required conditions is granted a subsidy by the French government, with the agreement that the truck is always to be at the service of the War Department in case of emergency.

Automobile Roads in Egypt.—To the activity of Lord Ribohner is due the construction of a fine automobile route in Egypt between Carro and Alexandria. The road is some 130 miles long and was practically finished some time ago. Although some of the intervening cities are already connected by roads, this is the only through route between those two cities, so that it will be much appreciated. It now appears that the Public Works Department is engaged on plans for a complete network of nain routes to cover the whole of Egypt, and those will be in charge of the government while the secondary roads belong to local authorities. Outside of military use, the plan will be of great economic value to the country in opening up innecessible districts. In other cases it will add to the facilities given by the Nie and by railroads, both for commerce and for touring. According to this, the day is not far distant when an automobile one make the trip from the port of Alexandria clear to the first extraction or a 6010 and in contributions of 6000.

## The Khedive's State Train

## A Benzol-Electric Train for the Governor of Egypt

By F. C. Coleman

T WO motor coaches (a saloon coach and a composite coach for the suite and attendants), each equipped with a bearol-electric set, have recently been supplied to serve as a state train for the Kbedier of Egypt The system of driving adopted differs

The system of dirichig adopted differs from previous forms in the fact that each of the two coaches is equipped with a combustion oughte, dynamo and electric motors, and the train can be controlled from either of the drivers' compariments at each end. The division of the machinery between the coaches possesses the following advantages: A better distribution of the weight is secured. When reversing the direction of travel, the pushing of the front coach by the rear coach is avoided; and it also becomes unnecessary to shunt the coaches. If a defect occurs in one of the combustion oughness or electrical machines, the train can be propelled at a reduced speed by the set which remains intext. The train is intended to travel at a speed of 40 niles per hour on the level, and the total train weight without passespers is approximately 100 tous.

The construction of the train is illustrated herewith Each casch is mounted on two two-sale trucks. The beauso-deective sets are mounted in the two trucks ranning at each end of the train, the four electric motors being placed in the center bogte trucks. The combustion engines are fixed to a special inner frame which is supported from the axles is supported from the axles is supported from the axles is supported from the ordinary double spring suspension of the coach body from the axles, a triple spring anspension is obtained be tween the coach body and motor, thus oliminating all vibration. The custine trucks are placed so far in front of the coaches that the engines and auxiliary machinery are completely exposed when the bounces are removed, the electrical matchines are accessed in through openings on the roof flower realistors are mounted on the roof accessed that councering place to the council of the council of the excession of the excessi

The setion coach conteins one large reception should and a private setion, both of which are luxuriously fitted up. It also contains a favatory, observation plat form and driver's compartment. The composite coach contains two second class compartments, three third class compartments, the contains two second class compartments, a leavatory and a corridor leading through the whole coach to the driver's compartment. In leavatory and a corridor leading through the whole coach to the driver's compartment. The two coaches have a vestibule connection with each other

Each machine set consists of a combustion engine with its maxiliaries, and the electric generator and exciter, the latter machines being coupled to the motor by a floxible teather belt coupling. The fourcylinder combustion engine has a continuous output of 12th horse-power at a speed of 700 revolutions per minute. It will operate either with lenzed or goodine. The valves are all situated on one side and are actuated by a common shaft. The engine is started by means of compressed air from an air tank. The cooling of the engine is effected by water circulated through a honey-comb radiator, mounted on the roof of the coacis, and in addition to the natural draft when traveling it is cooled by an electrically driven fan with a vertical slatt mounted on the coach

roof. The fase tank is suspended from the engine truck and the fuel is kept under the pressure of a neutral gas, nitrogen or carbonic seld, which is drawn from a steel cylinder through a pressure reducing device. This arrangement insures absolute immunity from explosion. The speed is regulated by a centrifugat governor. The regulator has a speed adjusting device operated electricatly from affe controller in the "out" position, by means of which the speed of the combustion engine can be reduced to approximately one third, when the

coach is stationary. By these means the noise caused by the motors when the train is not moving is appreciably reduced and, moreover, there is a considerable saving of fuel. The exhaust gases are led over the roof into

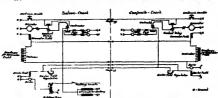

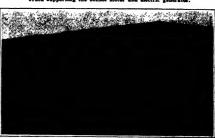

Diagram showing the system of electric connections.

Benzol-electric train built for the Khedive of Egypt.

Truck supporting the benzol motor and electric generator.

Driving truck fitted with two motors.

the open air through a stlencer suspended in the chimney by springs and facibly connected with the motor. The generator in each machine set has an hourly rating of 80 kilowatts and a continuous rating of 80 kilowatts, the exciter having a continuous rating of 85 kilowatts. Both machines are cooled by a fan mounted on the same sheft. The normal generator pressure is 300 volts, the exciter pressure sheing 60 volts. The generator has auxiliary poles and can be overloaded at starting with a current up to 800 nupsers. Each coach

is equipped with two series wound auxiliary pais motors, each having an hourly rating of 30 holes-power at 300 volts. The motors work the axies through granted having a ratio of 1 to 2.6. The control is effected by

regulating the voltage of the ators. The control of both as may be carried out in essetther of the drivers' on The system of connection is sh drawing. The met or circuits other, and the generator of one : feeds the two motors of the si so that heavy cable couplings are not required. There are the necessary safety precaution, such as fuses, overload release, and arrangements for breaking the di-cuit on releasing a push button on the concuit on recessing a push outron on the con-troller. The reversers operated from the master controller are placed in each coach for reversing the direction of travel. In the field circuit, the one exciter excites the two generator fields connected in parallel, through a common resistance the steps of which are gradually shorted cutted by the controller at starting, may be seen from the diagram, one these resistances is placed in ea i.e., one for each controller, so that only one of them is in use for each direction. The two exciter fields connected in arallel are fed in a similar manner from an auxiliary battery with a one hour capacity of 68 ampere hours at 66 volts, to which the second exciter is connected in to which the second exerter is connected a parallel. When the combustion engine is running at a low speed this exciter will be switched out automatically by a special switch, and when the speed is high it is awitched in again, so that in the first case battery works alone, and in the and case it works in parallel with the exciter, and can also be charged from the latter while the train is running. The lighting, signaling apparatus (consisting of a motor siren and gong) the battery ignition and other auxiliary apparatus are nnected to the battery.

The operation of the controlling near is as simple as in the case of a single coach, after the two bennol cuttines have been started up and the constant cretter voltage adjusted. Should any part of the equipment develop a defect, the system of connections can be attered in such a manner that the train will operate with the equipment of the other coach alone, this alteration being effected by means of a throw-over switch, which is sealed in its normal position.

Subsoil water has been a somewhat newlected factor in agriculture, yet it is the theory capital upon which the secons of the crops depends in a dry easen, as well as the source of brocks and rivers. Plate L.—Showing typical conditions along the edge of the Sun. From a photograph made with a spectroheliograph using the light of calcium.

## The Profile of the Sun

## How Invisible Solar Prominences are Studied by Means of the Spectroheliograph

By Frederick Slocum of Yerkes Observatory

I F the sun is seen through fog or dust, or is observed through a smoked glass, its outline appears to be perfectly smooth and sharp. One would little suspect that its profile is really characterized by such fantastic shapes as are shown in the accompaning liberations, which are from photographs by the author, made in the light of calcium with the Rumirord spectrohelio-graph of the 2frase Observatory.

Plate I shows typical conditions along the edge of rate I shows types i conducts along the edge or the sun. The general raged outline is the surface of the chromosphere. The larger forms are called solar prominences or protuberances. Plate II illustrates different types of solar promi-

Fig. 1 is a gaseous cloud resembling the appearance of a grow of baryan trees, rising to a height of 42,000 sulles, and extending along the edge of the sun for a distance of 240,000 miles. Prominences of this type may perist for weeks or even months. This particular one was observed for 55 days.

Fig. 2 shows a group of prominences in the vicinity of a sun-spot. The streams of matter from both sides are pouring directly down into a aun-spot, which was very near the edge on that day. The arc of the sun shown in the picture represents a length of 300,000 miles, which will give some idea of the distance to which the attractive induces of a spot may extend. Fig. 3 is a collection of arches and streamers, shown

in fine detail. Its height is 63,000 miles.

Fig. 4 resembles somewhat a turker standing 67,000 miles high. Another photograph taken two hours later shows what looks like a cloud of feathers floating off

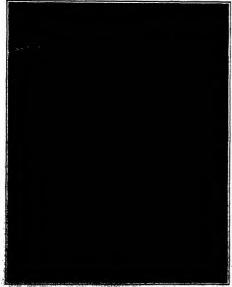

into space.

Figs. 5 and 6 are two photographs of the same prominence separated by an interval of 43 minutes. Within this time the prominence increased in height from 72,000 to 150,000 miles, corresponding to a movement s a second. Such rapid transformations are characteristic of the so-called eruptive type of promi-

Figs. 7 and 8 show the changes that took place in another prominence within 24 hours. Among other things, it may be noticed that the wind has apparently changed its direction. In fact, from prominences of this type some idea may be obtained of the general circulation of the solar atmosphere.

The existence of these prominences around the edge

of the sun was first detected during total cellpses of the sun. When the moon passes directly in front of the sun and has cut off all of its light just up to the very edge, these forms may be seen projecting out beyond the edge, shining brilliantly with a rose-colored beyond the edge, shining brilliantly with a ross-colored light. The only reason that prominences cannot be observed at any time by simply holding up a screen to cut off the direct light of the sun is that our atmo-sphere refracts and reflects the light of the sun, making the sky brighter than the proudsneces themselves. To an observer on the moon, which is devoid of atmosphere, the prominences, and even the stars by day, would appear against a black background of sky.

AND MARKET STATE OF THE PARTY O

Plate III.—The Rumford spectroheliograph attached to the great telescope of the Terkos observatory. The apparatus used for photographing solar promi-

In 1868 Janusen and Lockyer discovered a method of reducing the giare of the sky without, at the same time, reducing the light of the prominences, thus ren-dering it possible to observe these solar appendages at any time, and not merely during the few minutes of

It had been noted that the prominences gave a dis continuous or bright light spectrum. That is, if viewed through a spectroscope, a prominence would present several images of different colors, red, yellow, blue, etc., due to the light of hydrogen, helium and calcium chief constituent elements of the prominences. These images would be separated by appreciable intervals. If greater dispersion were used, that is, if a second were added, or a grating introduced, the dis tances between the various images would be increased, but their brightness would not be sensibly affected. The light of the sky, on the other hand, gives an

entirely different type of spectrum. It consists of fine lines projected against a continuous bright spec-If the dispersion is increased the total light is trum. If the dispersion is increased the total light is spread out over a greater area, and, therefore, the brightness of any one part is reduced. Moreover, the skylight gives dark lines exactly where the prominence gives bright lines. Thus, by using a spectroscope of sufficiently high dispersion, it is possible to see the prominences projected against a relatively dark back ground.

all ordinary purposes the slit of a spe scape is made very narrow, in order that the spectral scape is made very narrow, in order that the spectral lines may be fine and sharp, but for this purpose the slit may be open somewhat so that the whole of a small pruminence, or a considerable portion of a large promi-nence, may be seen within the opening. It widened to much, the background becomes too bright, so, in the case of large prominences, it is necessary to study them in sections. For such observations the slit of the spece is placed tangentially to the sun's edge,

by rotating the spectroscope through 800 degrees, the whole circumference may be examined
Ever since this method of observing prominences was discovered, daily observations of the sun's edge have been made in various places. In Italy a society was formed for this expressed purpose. Their publications Memoric della Società degli Spettroscopisti Italiani contain a practically continuous record of prominences for the past forty years. The published records are free hand sketches of the profile of the sun, showing the location and approximate form of all prominence for each day, and detailed drawings of those that were unusually large or active, to show the changes in form and size. At the same time, important but iess sy tematic work of the same nature was being done in England, Austria, Germany and the United States From these visual observations, two distinct types

of prominences were distinguished, the quiescent and of problements.

the eruptive These were observed to differ, not only in shape and activity, but also in composition and distribution. The quiescent prominences generally assume the composition of the co sume forms resembling clouds, or trees, or groups of trees, in size they vary greatly. Some attain the enormous height of several hundred thousand miles while others are even less than a thousand. In interal extent there is a corresponding difference. Some cover fifty degrees or more of the sun's circumference, while others may be confined within the limits of a single In this type of prominences, as the name im the changes are comparatively slow, and yet at times there are remarkable exceptions to this rule A prominence, which has remained quiescent for several days, may suddenly undergo some internal up heaval or explosion and be completely annihilated in a few minutes. The spectra of these prominences show that they are composed almost exclusively of hydrogen helium and calcium. They are found in all latitudes but a careful tabulation of the observations of many years shows principal maxima between 20 degrees and 25 degrees latitude in both hemispheres, corresponding with the positions of maximum sun-spot fre-The eleven-year period, manifested by sunspots, is also shown, but to a less marked degree, by the quiescent prominences

The eruptive type of promineness, on the other hand, closely associated with som-spots. They are rarely found beyond the limits of the sun-spot zones and they follow almost exactly the periodic and they rotion amost extertly the personal response, of sun-spots. They contain not only the hydrogen, helium and calcium of the quiescent type, but also frequently low, magnesium, titunium, hardum, sodium and namy other substances, chiefly marks. The crupic prominences supear as else, rockets, foundains, etc. They are generated property of the pr lu a few miunter

In 1891 dawned a new era in the study of promi nences, when Prof. Itale discovered a method of photographing them As in the case of visual observations, a spectroscope is used for this purpose, but when adapted to this special work it has been called by Prof. Hale a spectrobeliograph. It differs from an ordinary

spectroscope by having a slit in the focus of the camera, in addition to the ordinary slit in the focus of the collimator. The function of the second slit is to isolate any particular line of the spectrum, and enable the observer to make a photograph in the light of a single element. Thus, since prominences are composed chiefly of calcium, hydrogen and helium, it is possible to make a photograph of them in the light of any one of these elements. The H and K lines of calcium and the C line of hydrogen are best adapted to this purpose. The process consists of moving the image of the sun over the first silt, and at the same time, and at the same the first silt, and at the same time, and at the same rate, moving the photographic piate across the second silt. The same result may be accomplished by keeping the image of the sun and the plate fixed and moving the silts. When photographing the profile of the sun, a metal disk is so placed as to cut off all light of the sun except that which comes from the very edge. This method was used in taking the photographs

from which the accompanying illustrations were ma the great telescope of the Yerkes Obs

#### The Naval Airship By Carl Dienstbach

A FTER aircraft had shown their efficacy as scouts for the army even under the test of actual war, the navies of the world immediately took steps to use But while the soldier had done much in the ling the early toy aeroplanes into practical—albeit risky—machines, the sailor demanded an entirely novel sort of aircraft. Naval aeroplanes, because of the largeness of a naval theater of war, resulting from the fast movements of fleets, as compared to armies, and depende on the shore, are of limited usefulness in escorting a feet. An acrial vessel must leave shores far behind and cruise for days over the high seas. Only the mam-moth dirigible, a type, the development of which would probably have been delayed by the enormous expen of experimenting, held out any promise of fulfilling such demands.

Germany is the one nation which has thus far built navai dirigibles worthy of the name. Two appailing disasters have shown how thoray is the path she had entered. But while the first seagoing dirigible of Ger-many, a 22,000 cubic meter craft, the largest the Zeppelin factory, nated as the only entirely successful constructors of sizes above 14,000 cubic meters, would under take to build so late as a year ago, proved too small to withstand a real storm at sea (harder to avoid than on iand in the aissence of maritime weather stations), and while its more promising successor of 27,000 cubic meters fell victim to a totally unexpected internal catastrophe at the very outset of its career, there is no relaxing in Germany's efforts to make a dirigible practically the equal of a stemmer. This attitude, in the face of losses in officers of the highest efficiency equivalent to the cosmulties of a small battle is more easily understood, if the inducements these experiments out, are analyzed.

At sea aerial scouting assu mes an importance barely foreshadowed by the less that has been done on land. Owing to the level, uniform background it is impossible. sharing fog or heavy rain, not to see a vessel from shave at the remotest parts of the immense circle which extends to all sides for sixty-five miles even from the moderate height of 3,000 feet. It is easy to distin a warship from a merchantman, no matter how dimly The characteristics are too pronounced. It is als fairly easy to recognize men-of-war of different nationnairy easy to recognize mea-or-war of directin national stitles in that respect the United States have been most obliging to sirehips in adopting "maval landmarks" like finating Effect towers. But the difference between Engthst tripods and German "castle towers" for mill-tary masts is also marked Impressive, too, are the French smokewisches but it is often sufficient to recognize vessels as fighting craft by the way the smoke drifts from a fleet, and then to call for the which countersign. Radio-telegraphy has led to ludicro countersign. Maniference and Turkish armorelads in action exchanged wireless epithets, quite as the heroes of Homer roundly swore at each other in

Less unusual events may happen if a naval airship sights suspicious vessels from afar and an enemy tries to pose as a neutral before the aerial cross-examiner

to how me in neutral nervor the acreal cross-examiner.

It is worth noting how much neutral war vessels may now influence the issue by their mere presente upon the seene. This may lead to new international regulations, such as secret countersigns for neutrals, etc. (On tions, such as secret countersigns for neutrals, etc. (or hand the presence of neutral forces on a battlefield is obviously impossible.) It is not unlikely that a neutral who has posed as an enemy might be treated as an enemy. All this will be more clearly understood if we recall the more familiar conditions of serial secution recan the more raminar conditions or aertal security, over land, and ask: How would an army be treated who, without taking part in the fighting, would never theless decide the outcome by poshing for the airsoquits in this aertal age neutral forces play involuntarily the

20

part of the "neutral" Appearance on the Francisco, stde under Fraderick the Gessel. The second important point, which, makes mayed are structing so superior to military alreasesting depends, or the mobility of faceto compared with coldiers. The pe-tertial possibilities of an enduring, stouch several velocicounty possessions on a supermay, stated serial velocity of attri-free miles an hour, monthing stong and relability wireless equipment that covers sees 400 miles, are staggering. That is the craft which England really has to fear. Its mere existence is equal to doubling and trabiling a foreign navy. Without such "eyes," the English ing a rowing may, without such "gree," me anguar facet will either grope in the dark as a whole, or, being scattered to protect the shores, it will be defeated in detail by superior numbers. It will eath only an occa-sional glimpse of a foreign airship far away. But the emy's fleet will be two hundred miles farther away and always remain at that distance white safely convoying a numerous fleet of swift giant ocean liners crammed with soldiers to the "impregnable" shore. It is a very simple same of blind man's buff. Aeroplanes are not equal to this strategy. A condition sine que non, eventually, will be that aircraft can not only "craise" over water for several days, but have also enough lift-ing power or size to carry the ponderous gyroscopic ing power or size to carry the posserous groscopic compass and magnetic instruments with which to ascertain their locality, and consequently that of the enemy's fleet at all times and under any conditions. A good battery of long range automatic guns and machine rifles for aerophane defense will also be required.

In this respect and others it might be pointed out

that under modern conditions Britain's real danger has probably shifted from the Channel to Scotland, and that not the near, but the far foreign bases. which permit of an unobserved initial movement and a wide scope of action of the enemy's fleet, are now the a wine scope of action or the enemy sines, are now the formidable ones. Will this lead to many drownings of English aviators attempting to cross the German Ocean to Denmark and back without landing and to a pernauent "peaceful" blockade of the German bases by the whole English navy? Need Germany submit to such a blockade just outside its home waters? Germany in turn is handleapped by the conwaters: Germany in turn is minimizence by the com-fined nature of the watera near its bases; but its own navy might be cruising in the open, protected by aerial eyes, before the beginning of hestilities. To start transports in safety would be more difficult, but a fleet of swift transports might also manage to cruise early in the open under aerial protection. They could rendezvous from anywhere, the airships "herding" them by wireless. The whole coast from Emden to the Danish border would furnish suitable points for a steathly embarkation, with the help of strategical rail-roads. Once out of the North Sea the whole force would be absolutely safe as long as the airships held out. And there is no reason why a dirigible might not take aboard supplies from a ven el at s

#### Waste From Desks Goes Into Brushes

WASTE wood in the manufacture of school desks is now being used for the backs of cheap brushes, ording to the statement of the forest service.

A large manufacturer of school desks in Michigan had a considerable amount of waste material in sizes which were too short to enter into the manufacture of the smallest desks, and could not be utilized further with his machinery or in his line of work. This material was all hard maple in pieces an inch thick, a foot or so long, and about three inches wide; for a long time it had been consigned to the waste pile and sold as firewood. This waste amounted to from one thouas interesting the waste amounted to from one most sand to fifteen hundred board feet each day. A nearby manufacturer was using practically this quantity of maple, which he was sawing up into small pieces for making the backs of chesp brushes.

Members of the forest service, investigating methods of eliminating factory waste, conceived the idea that the blocks used by the brush factory could be readily secured from the waste of the school desk mannfac-turer, and on this basis got the two together. Arrangesuis were made so that the brush manufacturer new sees orders with the other firm for its raw material and what was formerly waste is now a sor

#### Moving Picture Records of the Balkan War

WAT

NE of the good uses for moving picture films is for recording historic events. Not long age the King of Roumania organization the production of a film of no less than \$0.00 yards length, this being a respondention of the Roumanian Russo-Crutician war which determined the independence of that country. The film will then be kept in the scribt each time of the real in In order to carry this out, the army lent \$0.00 men in uniform with arms and baggage, led by the efficient. Another case is that of the Italian government, which is actiseding all the films taken during the war in Tytpoil. In England the same is done for the films of the King's coronation events.

# A Plea for Careful Maintenance of Aeroplanes

the Editor of the Somerific American: The recent and fatality to Max T. Lille, the Chicago

aviator, at Galesburg, III., prompts me to present a few facts to the general public pertaining to the accident. That the accident was not caused by motor stoppas, and not due to suddee guest, is not generally known among lagmen, who have learned the details only from the none too accurate press. It is only the real student of aeronauties who, after investigati facts of the deplorable tragedy and its real bearing

The striking feature to be considered is, that the ac it was entirely avoidable! A report preceded by the investigation by Grover C. Loening, engineer of the Wright Company, states that the co se was old, weather beaten, and rotten. Many n sary parts had been forgotten or neglectfully omitte in the setting up of the plane, and many of the vital steel parts were rusted so that loose-play joints were bound. The wings were old and the cloth had rotted until it was a mere rag, torn at the slightest provocation. The spars were rotten in many places and abo-lutely unfit to undergo bending stress, having egitrely no pretense at strength. Is it to be wondered that the stress of a steep bank or a sudden dip should wre a machine, neglected as this one was, asunder?

Naturally, aviation as a science is the innocent suf-ferer of this preventable accident, both in the loss of one of its best loved and foremost airmen and in the prejudice of the criticising public. The lesson of thi tragedy is a pies for "greater care." If a steel part becomes rusty, it should be replaced. If the varnish is scraped from a spar, its needs should be attended to at once. Do not wait for an accident, perhaps fatal, to accentuate the faults of the machine! Discover the weak points and remedy them accordingly. Overc dence in his machine has been the Waterloo of many an airman. By the adoption of "greater care" many accidents can be avoided, and aviation will profit there EVERETT P. GORDON.

#### The Velocity of Hertzian Waves

To the Editor of the SCHNTIFIC AMERICAN :

In your issue of August 2nd I read with interest of the proposed co-operation between the wireless stations at the Eiffel Tower and at Arlington to determine the velocity of the Hertzian waves. The writer expresses a doubt, which seems to me well founded, as to the possibility of devising means to "flash back" the waves across the Atlantic in order to measure their rate of

It seems to me, however, that other means could be ed which would accomplish the same end with cailing for apparatus of such prodigious nicety of adcalling for apparatus or such productions interly or ac-justment as that suggested. Would it not be perfectly practicable to proceed as follows: Let the wireless transmitters at Washington and at Paris be coupled as usual to the clocks so as to send out instantaneous sigusual to the cross so as to send out mannianeous main each second, only let the clock at Paris beat seconds one tenth of a second or so behind that at Wahington. If now a recording apparatus with revolving drum be installed at each station, the two ticks could be compared on the same sheet, at each end. It would of course be necessary to protect the receivers from the direct action of the nearby sending tation, but that could readily be done by automatically switching of part or all of the antenna, and shielding what remained.

part or an of the societies, and smearing wint remained.

The record made on the revolving drum at Paris
would show two ticks approximately one tenth of a
second apart. But the lead of the Washington tick
would be diminished by the length of time it took for the waves to cross the ocean; while at Washington the lag of the Paris tick would be increased by the same amount. Thus, if the ticks for any given second were compared on the two records, there would always be a difference equal to twice the time required for ne a currecture equal to two the time required for the waves to cross the intervening space. As any ir-regularities of the clocks would affect both recorders allke, it is evident that this difference would be inde-pendent of all instrumental errors, unless there were a

pendent of all instrumental errors, nuless there were a difference in the "reaction time" of the two recorders. It would seem a rather simple caster, by interchange of instruments, to eliminate this error also. The same process repeated over land somewhere would rigid valuable information as to the effect of land and water on the waves. The distance measured could satisf be reduced, if a dram revolving several theorems or even a few hundred times per second be indust. Smallish. deed Smallie. American Mission, Harpoot, Turker.

#### Indian Summer at Home and Abroad

THE English meteorologist Abercromby introduced into the science of weather the important generalisation of "recurrence," under which term he brought together the numerous instances of the supposed tend-ency of certain types of weather to occur about the same time from year to year, independently of, and often in marked contrast to, the regular march of the ons. Thus in western Europe a period of unsea sonable cold is found to occur very frequently about May 9th to 14th; whence the days dedicated to Saluts ertus, Pancratius and Servatius, May 11th, 12th, and 18th, are known in France and Germany as the "ice saints." In England a similar period occurring traditionally in the second week of April is called "blackthorn winter," while in America we have a "dogwood winter" some time in May—"when the dogwood is in bloom"—and it is a common belief that the snowball ns bring cool weather with them to justify their

In England rains are looked for about Augu to Sth. These are the "Lammas floods." New England has its "January thaw." Both the Old and New World cling firmly to the tradition of an "equinoctial

The most famous case of recurrence, however, is the idian summer—so called in America, but in Europe reindian simmer—so called in America, but in surope re-plocing in a score or more of other names. It is "all-hallow'n summer," "old women's summer," "go-sum-mer," "All Saints' summer"—collectively—and well-nigh all the saints' summer individually, since in variiands it is linked with the names of Saints Luke, Martin, Michael, Bridget, Teresa, Wenceslaus, and so on, through half the autumnal calendar. The terminology is curiously confused with that of the spiderwebs that float in the air in mild autumn weatherwebs that float in the air in mild abrumn weather—
"gossamer," "go-summer," "gose-summer;" in German,
"Altweibersommer," which means both the webs and
the season of their occurrence, the two things being woven into the same fabric of folk-traditions.

The various cases of "recurrence" have been the sub ject of numerous investigations on the part of meteor-In Europe most attention has been paid to the slieged cold period in May-the "ice saints." the ningrest coun period in May—the "fee saints." Many long weather records seem to show that a cold spell does commonly occur in the middle of May, and it has been explained as follows: With the approach of summer the land warms much faster than the ocean, conmer the and warms much taster than in even, countries the thing of the taster relatively hot, the air above it rises, reducing the barometric pressure, while relatively high pressure prevails over the cold ocean northwest of the British Isles. The surface winds then flow from the cold anti-cyclone toward the cyclone; in other from the cold anti-cyclone toward the cyclone; in other words, cool northwest winds prevail over western Europe. A more searching study of the temperature records, however, has in necessity sears tended to dis-credit the existence of any well-defined cool period limited to particular days, or even weeks. It is evi-dent that the belief in the "iew saints" having once taken root in the popular mind, the occurrence of a cool spell at aimost any time in the spring would be readily accepted by unscientific people as confirming the phe nomenon as one of regular recurrence; just as almos any autumnat storm is popularly identified as the without much regard to the actual date of the equinox. Iconoclastic science long ago demolished legend of "the" equinoctial storm. So far as east ern North America is concerned, the autumnal equinox falls within the period in which West Indian hurricanes are likely to sween up the Atlantic seaboard. If the public chooses to call one of these tempests an "equi-noctial," it is entirely at liberty to do so; the name being neither more nor less appropriate than that of "Easter Illy" for a plant that blooms in the early and middle spring, but by no means exclusively on Easter

"Indian summer" in America is quite as elastic a term as "equinoctial." As the name of a type of autumnal weather it has a pretty definite meaning. As implying the more or less regular recurrence of a par-ticular season, year after year, at approximately the same date, it is misleading. One often hears peo-say, of a few days of fine, crisp autumn weather. der whether this is Indian su mer?" To which an other may answer, "No, it can't be, because we haven't yet had 'aquaw winter.' " The idea so firmly rooted in yet had 'squaw winter." The idea so firmly rooted in the popular mind that each autumn, as a rule, there is one period of cold, cloudy weather—with perhaps a flurry of snow—followed by one period of mild, sunny, hary days, finds no confirmation in the pressive records of the meteorologists: Indian summer weather, in fact, casy any, noted no confirmation in the prossic records of the meteorologists: Indian summer weather, in fact, prevails intermitteently over a period of two or three months. Thorest, at Concord, Massachusetts, notes in his "Antuma" that during the ten years from 1851 to 1860 weather of this type occurred on September 27th, October 7th, 18th, 14th, 31st, November 1st, 7th, 8th, Tith, 33rd, 25th, December 7th, 10th, and 18th. The indefiniteness of the term is even more strikingly brought out in Schaeders's analysis of the westher records of Milwankse, in the Monthly Weather Review for

September, 1902. (The same journal for January and February, 1902, contains the fullest of all discussions of Indian summer from the philological rather than the meteorological point of view.)

The European equivalent of Indian summer is a triffe less indefinite. A painstaking memoir on this subject, from the pen of Dr. Artur Lehmann, has re-cently appeared in Germany. Dr. Lehmann gives us. in the first place, an elaborate account of the terminology of the "after-summer." the commonest name for which in German is Altweibersommer ("old women's summer") In a great many countries and districts this season is, as we have said above, traditionally associated with the day of a particular saint in the autumn called with the any of a particular saint in the aniumn calendar; thus implying a more definite time of occur-rence than does the term "ludian summer" Dr. Leb-mann gives the reputed dates for the beginning of the which vary considerably with latitude, thus Russia has a "young women's summer" as early as the latter part of August, while the "Estate di San Marof Italy begins November 11th The author also gives us many interesting particulars concerning the association of the "after-summer" senson with floating spider-webs, or gossamer; a theme of picture-sque

A careful analysis of meteorological records shows that the occurrence of the Indian summer type of weather is most frequent over central Europe in the 55th pentad of the year; i.e., September 28th to October 2nd. It is easily traceable to the presence of a widespread area of high barometric pressure over the at east of its center, bringing mild southeasterly winds to the region in question, and atsoutheasterly wholes to the section in question, and at-tended by clear skies and strong insolution during the day. These conditions may persist for only a few days, or, occasionally, as long as four weeks

We must infer, however, from the facts presented in Dr. Lehmanu's memoir, that, as in the case of our own Indiau summer, the "after-summer" weather of Europe may occur intermittently through the antumn: but that the particular period of such weather that h coincide with various autumusi activities of the rural population is the only one that attracts general attention. From a meteorological point of view, in Europe as in America, there are probably several "Indian summers" in some years, while occasionally a year may have none. In other words, "Indian summer" is merely a convenient designation for the most delightful of all types of autumn weather

#### First United States Patent on Ice Making

THE first United States patent for the manufa-THE first United states partial to John Gorrie of of Ice, No. 8,080, was granted to John Gorrie of New Orleans, La. on May 6th, 1851, for a process of artificial production of ice, and the original patent and re now on exhibition in the United States Na tional Museum

They are especially interesting in that they cover completely Dr Gorrie's early method of making ice and his refrigeration system, which was the indirect process, that is, the cooling of an uncongealable liquid which in turn cooled other substances. According to the early custom of the Patent Office, the papers and the patent are written by hand on parchment, and ough now quite old, are nevertheless in excellent con ditton

In 1898 Mr George H Whiteside of Apalachicola, Florida, secured these papers which he presented to the Southern Ice Exchange, and for that organization de-posited them in the National Museum, together with a series of articles on the same subject which appeared in the Commercial Advertiser of Apalachicola, Fla. in the year 1844, as written by Dr. John Gorrie under the nom de plume of Jenner.

## The Current Supplement

O NCE again the plan of connecting England with the European continent is being agriated, with more promise of actual execution than ever before account of the latest project is given in this week's Supplement — Some tractors for farm service, exhibited and tested at the recent Solssons competition, are illustrated and described.—Dr A Gradenwitz writes on the manufacture of porcelain—R S Whipple's paper on modern methods of temperature measurements is concluded in this issue -E. D. Clark writes on the origin and significance of starch -The elimination of cinders from furnace gases is an important industrial problem. How it has been successfully solved in a large plant is shown in an illustrated article -F. E. Kaem scribes dial scales for the rapid weighing of merchan-

# Photography By Invisible Light

Things We Should See if Our Eyes Were Sensitive to Ultra-violet and Infra-red Rays

By Prof. R. W. Wood, Johns Hopkins University

THE TOTAL OF NO PARTITION OF THE PARTITI

Fig. 2.—Same subject as in Fig. 1, photographed with ultra-violet rays.

Di RING the past two years I have made from time tent our knowledge of usture could be extended by making photographic observations of various phonoments on the limit of the

known for many correction to the known for many corrections have been most exhaustively investigated, but up to the time at which these experiments were commenced no attempts independent of the many continuity like the many continuity like the total state of oldpars, like for the study of objects. It is obvious that a great part of our knowledge comes from simple observation by the eye, unalded by any optical instruments, but the eye is an interest and instruments, but the eye is sensitive only to a narrow range of the spectrum, for some of the rays that reach us from the sun and from our surfilledal lights make no largeresion upon the human realms. Now, inasmuch as these invidule raws are reflected from all objects in precheely the same way as are the rays of visible light, it seemed highly probable that if the range of sensitiveness of the eye could be extended so as to make use of these obscure rays, many new facts would immediately be revealed.

While this cannot be accomplished directly, we can, by the aid of photography, secure pictures which tell us how objects would appear if we could see them by

means of invisible light. For example, I observed that letters justined in Chinese white on a sheet of white paper, while absolutely invisible to the eye, came out coal-black when photographed with the ultra-violet ravs

During the past two years I have so far in improving the method that it is now adually possible to pilotograph the metallic vapor that rises from a drop of quicksliker at the temperature of the room, though the presence in the air could hardly be detected by the most redined methods of chemical analysis. This savors aimost of spitly pholography, experiments with the "aura", and such other fantastic fablics of which we read, and I feel sure that there will be renewed appeals from the writers of the numerous letters. I received shortly after the results of my first experiments were made justice, arging me

to devote my attention to the photography of the spirits of the departed by means of ultra-violet rays, for "hope springs eternal" And now a word or two about the ultra-violet rays

And now a word or two shout the uitra-violet rays as an introduction to my subject If n beam of suight is passed through a prism, a rain-how band of colored light is thrown upon the wall, or, as we say,

the prism has decomposed the white light late its elementary colors, forming a spectrum. If we receive this spectrum upon a photographic plate, we find that it is much longer than it appears, for there are rays beyond the violet that do not affect the eye, but that blacken the photographic plate; and the same is true in the region beyond the red, though to photograph these rays we require a specially sensitized plate. When we employ a prism cut from a crystal of quarts instead of giass, we find that the spectrum is still more extended in the ultra-violet region, the invisible portion being much longer than the visible. In other words, giass, which we are apit to regard as one of the most transparent of substances, is absolutely opaque to the shortest ultra-violet waves of light; and if we wish to make use of those ray if no un work, we

must employ a camera fitted with a lens of quarts, and must, in addition, prevent all rays of visible light from entering it. This is not an easy matter, for practically every substance that is opaque to visible light is still more opaque to the ultra-violet. To this there

Fig. 3.—White phlox, white geranium and honeysuckle in glass vase, photographed with visible light (at the left) and ultra-violet light (at the right).

are however one or two exceptions. Some ten years ago I discovered that a certain aniline compound with a long name (nitroso-dimethy-laniline), while opaque to the bine and violet actinic rays, was very transparent to the ultra-violet, and by combining this substance with other media, it was possible to prepare screens,

Fig. 4.—Photographs of reflectors, showing that nickel makes the best mirror for ultra-violet light.

or ray filters, us they are called, which transmitted only the invisible rays.

These ultra-violet screens have been extensively used in investigations made with invisible rays, both in this country and abroad, and to a certain extent in astronomical photography. A more remarkable case, how-

Fig. 5.—Portion of the moon photographed with yellow, violet and altre-violet light (left to right). Note the spot indicated by the arrow,

ever, is that of a thin film of metallic silver deposited on a plate or lens of quartz. Such a combination is transparent only to the invisible ultra-violet vays, which are completely absorbed by glass; and by stimply providing a camera with a lens of this description

g a camera with a lests of this description we can at one photograph objects as they would appear in ultra-violet light. We may use either sun-light or the light from one of the recently perfected mercury are lamps made of funed quarts, the ultraviolet radiations of which are especially powerful.

The complete opacity of giasa to these rays is beautifully illustrated by the photographs reproduced in Figs. 1 and 2. The subject is a microscope, covered with a transparent giasa bell-jar, atanding in front of a sheet of withe paper. The invisible rays used in this case came from a mercury are in a quarts tube, and we see that the hell-jar is as ogaque to them as if made of elouy. Only the two images of the mercury lamp reflected from the outer surface appear, the microscope having vanished; and the shadow is as black as if thrown by a metal ball.

If our eyes were sensitive only to the ultra-violet region, our houses would have to be provided with open windows, for glass, celluloid, and all our common transparent substances would let in no rays of light by which anything could be seen, the, we exclaim, that this mistake was not

How fortunate, we exclaim, that this mistake was not made; and yet it could not very well have been otherwise, for the materials out of which nature has developed our eyes are themselves opaque to the rays, and no evolutionary process could be expected to develop a retina sensitive to rays which never reach it. I have

found that many, though by no means all, white objects appear black in ultra-violet light, as for example, common white garden flowers. This opens up the interesting question as to whether we have selective coloring in the invisible region of the spectrum, or, in other words, are all white flowers equally dark in ultra-violet light, or is the absorbing pignent different in different flowers, and are there variations of the spectrum region absorbed? These questions are answered by Fig. 3, where we find reproduced two photographs of the public and white gerantums and honey-suckie. The with peaks of the honeysuckie and phice

sucks. The white petals of the honeysuckie and phlox come out dead black in the latter, while the gerunium are much lighter in tone. By employing a spectroscope I have found that the absorbing pigment is different in the two cases, so that we do in restly have selective coloring in this region, and we should be able to perceive coloring in this region, and we should be able to perceive coloring in this region, and we should be able to with the blossoms, if our eyes were able

to perceive color differences between various white blossoins, if our eyes were able to observe them by the obscure rays. The significance of these differences and the part, if any, they play in the economy of the plant are questions to be answered by the plant physiologists, and I prefer not to speculate about them.

to operator about term.

Ultra-violet photography has already furnished new data in astronomy and astrophysics. Prof. Hartmann of Officingen has recently photographed the great nebuta in Orion through one of the stimaviolet coriens which I described in 1858, and at the mass time by visible likely such has found that the sheeps of the trade-one as an ensawer composing the abolia, and different in the two costs. In class words, the gate which relificates the stimulation of the control of the costs of the cost

THE RESERVE OF THE PARTY OF THE

With the equipment the mechanic of modics when photography to the two photograments (if year. Survivanous, france while a many features the mangaints often plants, showing the distribution and the two games which form the mobile is a most extitute manuse.

The to the present flow my eyn investigations have been continued to the moon, as my instrumental applicance, is not powerful enough or estimates the well mounted to enable as to de much with the planets, though a few attempts have been made with the party.

with Saturn.
It may seem stronge that while we can

In the most distant stars, our ignorance regarding the constitution of our heavest neighbor, the moon, is absolute, so far a say direct evidence is concerned. There is every probability that it does not differ markedly in composition from the earth, but the spectroscope tells no nothing, for the moon is cold and shines.

as nothing, for the moon is cold and shines by nesdered light. Many terrestrial sixth presents of the present o

serier experiments, however, I noticed that a little black spot appeared close to one of the lunar craters in all the photographs taken with ultra-violet light, while no trace of it was visible in pictures made by yellow light, which represent about what we see with a vinual

ignit, when represent nous what we see with a vasual cleacope. This seemed very important, and I at once commenced experiments with a view of finding out, if possible, what the dark material might be. It was first necessary to get larger and better photographs, and secondingly I had made a concave reflector, sixteen inches in diameter with a focal length of twenty-six feet. It was useless to still yet this mirror in the usual way, since a pollabed silver surface reflects only about four per cent of the ultraviolet rays with which the work was to be done. This is very nearly the reflect.

ing power of ordinary glass for visible light. Nickel, however, behaves very much better in this region, reflecting about fifty per cent of the ultraviolet, though very inferior to silver as a reflector for visible light. This remarkable difference in the reflecting power of the two metals is well shown by the

Fig. 6.—Velcanic taff with invisible deposit of sulphur, photographed with

photographs reproduced in Fig. 4, which were made in the course of some preliminary experiments on a methdo of making astronomical reflecting telescopes autiable for uitra-violet work. The photographs are of a shallow risas dish which was silvered on the inside

Fig. 7.-Photographs of mercury vapor made by ultra-violet light.

by the chemical process used for conting telescope mirrors. This film of sliver made the surface of the glass a conductor of electricity, and by dipping the lower portion in a beth of nickel sulphate a film of the metal was deposited by a battery, after which a small patch of the silver film that remained uncoasted

Fig. 8.—How a raised check can be detected by ultra-violet light.

with nickel was removed from the glass by scraping the surface with a pen-knife. In the photographs the sitemed part is marked Ag, the nickel  $N_i$  and the patch of clear glass G. The dish was mounted near an open window in such a position as to reflect the light of

the sky into the camera, and four phototraphs made of it, one by ordnary light and three by ultra-violet, using silver films of different thicknesses on the quarts lena, to cut off the visible rays. In number 1, made by violet light, we see that dilyer referes much more powerfully than the nickel, while the patch of clear gisse is almost black, owing to its very low refecting power. In number 2, made by the mixture of violet and ultra-violet rays, which we utilize when we employ a thin film of silver as a ray filter, we find that the silver and the nickel have about the same refereing power, while in numbers 3 and 4, taken by ultra-violet of increaswe find that the silver referes no better

ing purity, we find that the silver reflects no better than the clear glass, appearing quite black. Nickel having thus shown itself to be a suitable metal, a method was worked out for depositing it on the large mirror, and the studying of the moon was resumemirror, and the studying of the moon was resume-

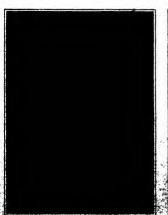

the studying of the find moon were made by light taken from three different regions of the spectrum, the yellow, violet, and ultra-violet; for it had occurred to me that it would be interesting to apply the method of three-violer photography to the case. In the usual method of making color photographs, three negatives are made through color screens corresponding to the three primary colors, and the final color picture results from them, each positive being stained with a prinary color. In the present case, however, 1, employed ultra-violet light in making one of the three original megatives, and then built up the color-picture in the usual manner. The printing operations were done for me by M I vess, the planers

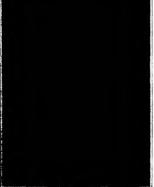

in work of this kind, and the result was n very beautiful transparent picture of the moon, in which the local differences in its reflecting power for the three regions of the spectrum utilized were strongly differentiated in color. In this picture the dark spot near the crater Aristarchus, about which i shall have more

to say presently, came out bright blue, while some of the snaria or gray spots came out reddish in tone, and others greenish, indicating differences in the unherst composition of these areas. As to the nature of the Aristarchus spot 1 have already reached a pretty definite conclusion. It is well shown in the ultra-violet photograph reproduced in Fig. 5. Referring to these three pictures of the same portions of the monit's surface, on which I have indicated the cratter Aristarchus by an account means that the indicated the cratter Aristarchus by

an arrow, we see that he pleture taken by yellow light there is no trace of the dark spot; in the one taken by violet light it is lust beginning to appear, whereas it is strongly developed in the one taken by ultra-violet. The question to be answered

(f'oncluded on page 385)

# A Disease of Old Leaden Art Objects

## How Corrosion may be Retarded by a Protective Coating

By Jacques Boyer

A FEW years since Prof. Cohen of the University of Utrecht showed that tin is subject to a disease which can be communicated by contact from one object to another. The experiments of the Dutch chemist proved that this disease of tin is a molecular transformation, in the course of which the white metal turns gray, increases in volume by one fourth, swells, dis-integrates and finally falls off as an exceedingly fine

Prof. Camille Matignon of the College de France at-tributes to a disease of very different character the spontaneous and progressive destruction of old leaden seals, pendentives, brooches, drinking cups and feeding cups for birds, medals, pilgrims' badges and other art objects The curator of the Musée de Cluny, having made the surprising discovery that some leaden articles in the collection were gradually becoming corroded and falling to dust, while others remained intact, submitted the matter to Prof Matignon, who, analyzing the powder collected in several cabinets, found that it con-sisted chiefly of carbonate of lead, and gave the following explanation of the phenor

se leaden objects that are subject to the disease contain traces of chlorides which, by catalysts, render the metal susceptible at ordinary temperatures to the simultaneous action of the oxygen, humidity and carbon e present in the atmosphere. The catalyzer then is to its initial state, and the process is repeated indefinitely This theory is confirmed by Prof. Matig-non's detection of chlorides in the diseased specimens, and by his production of the disease in healthy speci mens by artificially infecting them with chlorides.

Several cases of this curious metallic disease are illustrated in the accompanying photographs. Fig. 3 shows a Florentine medal of the sixteenth century, by Vittore Pisano. Behind the head (that of Alphonse d'Aragon) appears a white spot, which marks the commencement of the disease. Fig. 4 shows a well pre-served pilgrim's badge of the twelfth century between two pilgrims' badges of the same period, which have

Fig 2 shows a birds' drinking cup in perfect condi-tion beside a birds' feeding cup of the fifteenth cen-tury, which is fulling into dust. The group representlng St George and St. Valerie, in Fig. 1, is greatly deteriorated, and so is the shorter of the fourteenth century pencils, while the longer pencil has been protected from the disease by a coat of varnish.

The presence of chlorides in old leaden

objects is easily explained. Many of these objects have been buried in the earth, and the varying proportion of chlorides found in different specimens is due to their longer or shorter sojourn in soil infiltrat-ed with salt water. The sea salt prob-ably causes the corrosion of the lead by forming an alkaline carbonate or bicarbonate which is afterward reconverted into chloride, or an oxychloride of lead may be formed. This hypothetical cycle requires an alkaline reaction for the in-termediate products, and Prof Matignon has detected alkalinity by depositing a drop of phthalein solution on the surface

of a corroded sheet of lead.

As a remedy, alle chemist recommends Bee SCIENTIFIC AMERICAN, June 25th, 1910. the application of a transparent celluloid varnish to leaden art objects. This protective coating retards the progress of the corrosion by excluding the air almost

#### Making Two Automobile Lamps Do the Work of Four

A MONG the more recent developments in the automobile field, it is interesting to note that side
lampe—unmistakable evidences of the horse-drawn forbears of the modern horseless carriage—slowly but
surely are disappearing; and though the development
is a perfectly logical one, the combination of head
lamps and side lamps as now practiced by a number
of troublant results are results. superficially solved in the rush to exploit the latest innovations demanded by the buying public.

When electricity as an illuminant for automobiles

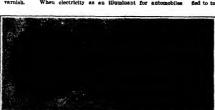

Fig. 4.—Pilgrims' badges of the twelfth cantury. Two of these are whitened by corrosion, while the third is intact.

factor of equipment and practically without exception was hastily adopted and advocated by manufacturers the possibility of eliminating side lamps was quite over-looked—a fact which is all the more astonishing in view of the present day tendency toward the elimination of all that is not absolutely neces tion of all that is not absolubly necessary for the proper operation of a car and for compliance with the laws regulating motor vehicle traffic. Now, however, light has broken in on designers and made clear that as far as the law is concerned, and also as far as the operation of a car is concerned, two lamps are all that operation of a car is concerned, two lamps are all that are required, neglecting as outside the present question the rear lamp. But, needless to add, the necessity for combining in those two lamps the functions of four lamps also became apparent and the manner in which the problem has been attacked in not a few instances makes plain that there is room for much improvement. In eliminating the side lamps, it is necessary to make provision in the head lamps for the production of con-

rably less light than ordinarily would be produ sideraby less light than ordinarily would be produced by Yull sixed bulbs and the full pressure of the bettery, and there are several ways in which this can be done. Probably the simplest way is to introduce a small rheo-stat into the circuit, but this method is open to the ob-jection that the rheestat consumes current that might be put to some better purpose; it represents a needless waste of current, in other words.

Another method is to provide a switch with which ctions of the lamps, normally multiple who full candle-power is desired, can be changed to series temporarily. In this case the lamps would consume considerably less current when "turned down" than is considerably less current when "turned down" than is normally consumed when operating at roll brilliancy. This method, though better than the method involving the use of a rheostat, has the disadvantage that the failure of one lamp of necessity means the failure of both. Apparantly, therefore, nothing remains but to make provision within the lamp for the reception of two bulls—one of say 16 to 21 candie-power for town service; and this six what has been done by several magnitudenters. Obviously, two bulbs cannot be placed in the oriented focus of a retrability reflect, one begins the principal focus of a parabolic reflector, one being large and the other small, even if this were desirable. But it is not desirable for the effect of the small bulb, if placed directly in wie focus, which would be magnified to too great an extent. It follows that the smaller

of the two bulbs must be placed some-where other than in the focus and this reduces to some extent the efficiency of the mirror when the larger of the bulbe is in use. The decrease in efficiency may be to all intents and purposes negligible, but it exists. When the side lamps are removed there is removed also a warning of the presence of the car to those approaching from the sides. Even when side lamps have no side "window" through which their light may shine and thus serve as a warning, their beams, even when but faintly reflected from the angine hood and fenders, serve this purpose. But when smaller builts are placed in the head lamps their beams are not always intense enough

# Inventions New and Interesting

Simple Patent Law: Patent Office News: Notes on Trademarks

A New Union for Piping Syste MODERN demands necessitate higher water and steam pressures in large buildings, greater hydraulic pressures in mills and factories, and generally harden conditions in all piping systems. This is substantiated by the fact that all pipe manufacturers have adopted standard full weight pipe, refusing longer to put on the

market the light weight merchant pipe.

The fittings ordinarily used are heavy cast iron, and the couplings furnished with the pipe are made of forged iron On account of the requirements of form and the abuse given them, unions used or piping systems up to the present time have been made of malicable iron, and have been the weakest link in the piping sys-

Mr. Charles A. Dies of Chicago, Illinois the inventor of a new union, in commutth many others, was aware of the li tations of existing pipe unions, and saw that there would be a big field for one which would give satisfactory and uni form service, and which would me ever-increasing demands for stronger and better piping systems.

Other inventors and manufacturers of

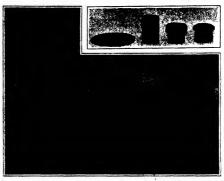

unions, like Mr. Dies, recognized that the n was not suitable for the service and have made many different attempts to improve the article. Most of these at-tempts were along the lines of changing sign, although in some case forged steel unions have been made suc constully. These eliminated most of the defects of cast unions, which had a tendency to be full of blow holes, cracks or shrinks which made them undependable Forged unions overcame also to some extent the trouble with all malleable union due to their unequal expansion and contraction with the steel pipe with which they are connected. The great trouble with the hot-forged union, however, was that its cost was so great as to make it ost prohibitive.

largely used to-day, the only objection being that they are too heavy and cumbersome, as well as very expensive.

Mr. Dies, using his knowledge of metal drawing and forging, went at the problem of devising a stronger union by choosing a new material, instead of trying to make a better union than the others from a cast ing. He accomplished this by drawing the various parts from cold flat strips of rolled open hearth steel. We illustrate four stages in the process of forming the male end. The first operation punches from the flat strip, a disk or blank of suit able size. This blank is then cupped and redrawn into a deep cup or cylinder, from which the bottom is punched to form a seamless tube, as shown in the second illustration. One end of this is then folded or rolled back un itself to form a reinforcement for the seat pictured in the next figure. Further operations co press and shape this seit, and put the beading on the lower end as see fourth engraving.

The female end is formed similarly, the differences coming in the last few oper-ations, which alter the shape of the seat The seat or joint between the en union consists of the hardened and densi union consists of the marcener and gener-fied seat of the male end opposed to a soft brass seat or cushion drawn from dead soft sheet brass, and forced into place in the fluished female shd. This

place in the fluthed female end. This gives an ideal combination—a hardened steel used against a not breas seat. All the forming operations are per-formed upon the metal while it is cold, and the seats are bot machined or ground in any way, but despend for their accuracy and form entirely upon the pressure ar-pited to choose in the general. Score of

these presses are illustrated in the accomination threading is done, so that every part of banying engraving.

panying engraving.

The threading is done in specially constructed machines and the internal threads on the male and female ends are tapered to a Briggs Standard pipe thread, while the threads on the coupling nut are cut straight. The entire union, except the

Some Old Cork Extractors THE necessity of some form of cork ex-tractors is experienced by all, and it may be interesting to review some of the well known implements shown in the ac-

pictured being found among the expired

In A we find a device having a shank ed at its lower cud to penetrate through a cork, and provided with a short pivoted cross bar for ulining with the cork, but turning at a right angle to with draw the cork.

The corkserew B has the handle pivoted to the screw part and a prop is also pivoted to the bandle and it may be rest-ed against the bottle lip to form a fulcrum for the handle so that the last can operate as a lever to pull the cork, while C illustrates a simple wire cage for withdrawing corks that have been forced down into a bottle

A double lever in scissors shape is presented in D. and this can be used in connection with any handled corkscrow. etch E shows a stand to rest upon a bottle, and having a threaded shaft carrying the screw and a separate not operating on the threaded shank to pull the cork

Simple extractors having bludes to project down on opposite sides of the cork represented in F and G. shows an extractor in which a stand mounted on the bottle neck has at its up-per end a windluss connected by a chain with the corkscrew, so that it can exe force to pull the cork.

In I is shown an extractor adouted to be secured to a beach or counter and sup piled with a hand lever, whose rack seg tion to force the corkscrew into the cork. and when reversed, to pull the cork out of the bottle so as to free the cork from the screw.

J represents a novel form of corkscrew which can be folded as shown in the s er engraving to conveniently carry in the pocket, and can then be opened as shown in the larger one, to operate first as a andled corkscrew in turning the serous into the cork and then as a lever in extracting the cork from the bottle; and K presents a bench or counter extractor in which a screw turns into the cork and a spring when compressed aids in drawing

## Notes for Inventors

Fillings for Artificial Dentures.-- In patent No. 1,070,442, Ernest Fogg of New-castle-upon-Tyne, England, provides separate filling-pieces which fit and are secured in the interstices between adjacent teeth and fill such spaces

An Imitation of Pieced Fur Skins. An imitation of Pieced Fur Skins.— Richard J Steiner of Philadelphia has patented, No. 1,009,588, a mothod of producing mitation pieced fabrics in which the nap of a pile fabric is laid in certain sections in a different direction from other ctions with the individual sections subdivided by suture lines formed in the nap of the fabric

A Self-releasing Bowling Ball Handle In a patent, No. 1,068,389, to John W. Hyatt of Newark, N. J., is presented a bowling ball handle which has a movable device for locking the handle to the hall. A cord connects the device with the wri of the bowler so that when the handle is released in delivering the ball the cord will operate to release the movable device free the handle from the ball

Multi-color Lights for Moving Pictures. Multi-color lights for moving rictures.

—A projecting apparatus for moving pic-tures has been patented, No 1,070,699, by Isidor Kitsee of Philadelphia, in which a plurality of electric lights each producing a light of different color from the others, and which may be extinguished and and which may be extinguished and energized in succession, said lights being controlled in a predetermined order by means operatively related to the film advancing means.

## Co-Founder, With Darwin, of the Modern Theory of Evolution

By Benjamin C. Gruenberg

THE remarkable fact that two men at opposite ends of the earth had worked out, unknown to each other, an identical solution to the problem of the genesis of species, has been so often told that it hardly needs to be repeated. Each of these two tens, with a modesty that is rare even among accentists, constantly insisted that all honor for the great discovery was due to the other. For more than the state of the state of

jesionsy. One of these men, Charles Darwin, died in April, 1884; the other, Alfred Russel Wallace, has just passed away.

Alfred Russel Wallace was born in Usk, Mommouthshire, England, on January 8th, 1873. He received an elementary detection for a cycle of the center of the control of the

new forms. He cultivated this interest so that out of it diveloped a large part of his life work and a large part of his life work and the collegate Institute at Leicester. This was an unportant year for him, as in it occurred a few trifling events that turned the whole course of his life. It was here that he hecanne acquainted with Henry Weller Bates, a clerk in Allsouph hereor is here the second of his life. It was here that he hecanne acquainted with Henry Weller Bates, a clerk in Allsouph hereor is here the second of his life. It was here that he had not a strong deare to vasit the tropics, a dealer strengthened later by reading Darwin's account of the worage of the "Pleagle," and here that he read Malthar's "Peway on Population."

## stography by Invisible Light

(Concluded from page 251.)
was; "Can we find any terrestrial mineral

which behaves in the same way?" I photo graphed a large number of specimens of rock, many of them of volcanic origin, and finally found one to reproduce the behavior of the Aristarchus spot almos exactly. It was a yellowish gray volcanic tuff, identical in its appearance with an-other specimen of tuff, which, however, did not show the peculiarity of photographing dark in ultra-violet light.

I next made a chemical analysis of the small chip, and found that it contained

small chip, and found that it contained from and traces of sulphur, but photo-graphs of rocks stained with irou had shown that the iron stains came out equalty dark in violet and ultra-violet. There remained the sulphur, however, and to test this point a very thin deposit of sulphur invisible to the eye was formed of sulphur invisible to the eye was formed on the surface of the larger piece of tuff, by directing a jet of sulphur vapor against it for a second or two. The fragment, when photographed by the three different when photographed by the three different types of rays, showed no trace of the de-posit in the yellow picture, and only a faint trace of it in the violet one, but in the ultra-violet picture the deposit came out quite black, (See Fig. 6.) This makes it appear very probable that the dark deto sulphur, or to the presence of rocks containing sulphur. Its immense exten makes me think, however, that it is an actual deposit thrown down by an im-mense blast of gases from the crater. The discovery of sulphur in the vicinity

of a lunar crater is of considerable im-portance, since there has been a good deal of discussion as to whether the so-called "craters" are really of volcanic origin Should further investigations reveal the ce of similar deposits in the vicin My of other craters, it would be a strong argument in favor of the volcanic theory because sulphur is almost invariably found in regions which either are, or have been, centers of volcanic activity. It is a curious circumstance that but one of these deposits has been found thus far on the moon. Other smaller ones doubtless exist and can be picked up with a mor owerful reflector

In the laboratory I have been carrying on a variety of investigations with invisi-ble rays. These for the most part have tr do with rather abstruce problems in physical optics and spectroscopy, and I shall mention but a single case as illustrating mention but a single case as illustrating how the ultra-violet rays can be utilized in rendering visible the vapor given of by a metal, even at the temperature of the room.

Mercury is known to give off a vap that is very injurious to the health of workmen exposed continuously to the fumes. But it is of such extreme tenuity that a volume of air represented by a cube measuring nearly eight feet on each ide, after it has taken up all of the vapor it can hold, contains only about a cubic inch of pure mercury vapor, such as is given off from the boiling metal. Not-withstanding the fact that even the pure vapor is absolutely invisible, and as tran parent as air, it can, even when diluted with 800,000 parts of air, be photographed by the ultra-violet rays given off from a

by the ultra-violet rays given out from a new type of lamp I have designed to meet the special requirements of the case. This lamp, which I have named a reson-ance lamp, is nothing but a small bulb made of fused quarts, highly exhausted and containing a drop of mercury. The vacuum in this bulb is as perfect as can be able to the party meeterial athermore. be obtained by any mercurial air-pump and yet I have found that, if the ultra and yet I have found that, if the ultra-violet light from a mercony are be con-centrated to a forms at the center of the vacuous space, the lighty parefield mer-ters are reported by the substantial of substantial that of feeble intensity, but or great purify. To this faith light emitted by the bulls the vapor of sept-sary is quita opeaus, so much so, in fact, that we say photograph the vapor gives off from the metal-at venue temperature, hat is shown by Fig. 7, in which we have two persons of a, small quarter facts,

# Hupmobile

Now Europe claims half of all the cars we can build for 1914

When we designed the Hupmobile we made it essentially an American car, for

But Europe thinks the American Hupmobile such a good car, and so well suited to European requirements, that it stands ready to absorb half of the coming year's output of 1914 cars.

can you imagine a tribute higher than this; or a more positive confirmation of our belief that the Hupmobile is the best car of its class in the world?

The Briton, the Frenchman, the German, pays \$200 to \$400 more for his Hupmobile than you do because he recognizes its high quality and its operating economy.

As the Hupmobile buyers of South Africa, Australasia and New Zealand, where the Hupmobile has overcome at anti-American prejudice even stronger that that which exists in the European countries.

And in the Philippines thousands of miles from home the Hupmobile is as truly the car of the American family as here, as shown by the domination of its name on the registry lists. Thus the belief that the Hupmobile is the best car of its class in the world rolls on to practically every section of the globe where automobiles are used.

Noer and us to arginal how a United States Region will pay for itself. (This is our Pair year in the Manufacturing Business) UNITED STATES ENGINE WORKS, 488 W. 15th Street, CHICAGO containing a droplet of mercury about the size of a pin-band. This tiny drop gives off its vapor, which diffuses into the air in the finak, rendering it opaque to the light from the resonance lamp; conse-quently the air in the flank appears like dense black smoke in the photograph. The third picture in the same digne is a photograph of the vapor rising into the air of the room from a small drop of mercury placed on the top of a cylinder of brass, which was slightly warmed to cause the vapor to rise like smoke. Th photographs show us that it is possible by means of photography with invisible rays to study the behavior of a metallic vapor at very low pressures with great Ultra-violet photography I have found furnishes us a means of detecting altera-

s made in manuscripts and so-called leed checks." The best chemical ink "relead checks." "raised checks." The best chemical inserances remove the writing and leave absolutely no visible stain or other evidence solutely no visible stain or ourse evuesues upon the surface of the paper, and photography, by any of the usual methods, shown no evidence of tampering. If however we photograph the manuscript with ultraviolet light, the spot upon which the craser has been used shows up in the price. ture as a dark smudge, for the cher has given to the paper the power of absorbing the invisible rays, just as ordi nary ink causes it to absorb visible light.

A sample of a raised check was prepared for me by a well known authority on questioned documents The check originally called for twenty-four dollars, bu by erasing the heavy ink line drawn after the twenty-four and insertion of the word hundred. I was unable to detect any sign of aiterations and the cashler of one of our largest banking houses, to whom I showed it, said that it appeared to him to be all right. The photograph made with uitra-violet light told the story however in a manner that would convince any jury. The original writing and the ultra violet photograph of it are reproduced in Fig. 8.

The advantage of this method lies in the fact that the manuscript is not in-jured in any way by the examination, as is the case when chemical treatments are resorted to to show the use of an ink eraser, for it is often of importance to conceal the fact that the document has

een questioned.

In the case of a certain disputed docu ment which was submitted to me recently, the ultra-violet rays actually brought out traces of the erased words. A mercury iamp of fused silica was used for illuminating the manuscript, and the quarts lens used for photographing it was silvered with a film thick enough to render a tungsten lamp invisible through It.

My experiments with the infra-red rays ay experiments with the intra-red rays have been confined thus far to the photog-raphy of landscapes, though I have no doubt that interesting data could be ob-tained by-applying the method to celestial photography, for these rays have a re-markable power of penetrating a planet's atmosphere without suffering diffusion. In photographs made by the infra-red rays, green vegetation in full sunlight rays, green vegetation in full sunlight comes out as white as snow, while a clear blue sky appears almost as black as mid-night. This is due to the circumstance that the rays come through our atmo-sphere without being scattered, for it is exteted light that gives the sky its color and luminosity. I have recently obtained some very fine examples of these infrared photographs in Sicily and Italy, some of them being extremely decorative. In Fig. 9 we have a view taken at the bottom of the Latomia of Syracuse. This is the ancient quarry, in which the conis the ancient quarry, in which the con-quered Athenian army was imprisoned, and the view was taken looking out through the mouth of a cave-like forma-tion at a group of young aimond trees, with which the bottom of the quarry is overgrown. The green folloge comes out white, as if the trees were in blesson, and the sky near the top of the picture is almost as dark as the deep shadows with-in the cave. It is only a were clear him.

# KEEN KUTTER Table Cutlery

The finest carving sets and the most beautiful and substantial table knives and forks bear the Keen Kutter trade mark.

Let this famous eign be your guide in buying, and you will grace your table with the best.

A Keen Kutter carving set is a thing of beauty—each sharpening steel-per-fectly balanced, exactly tapered and finely tempered.

Knives and forks for individual use are of the same high grade steel and triple electro-silver plated for long wear. Much of this exquisite cutlery has mother-of-pearl or stag-horn handles. All is finished and put together to pive service.

> Remember that everything bearing the Keen Kutter trade mark is guaranted—not in a meaningless, per-functory way, but by a real warranty that says you must be suited or your money will be re-turned.

it down to the horizon where the haze is at down to the normal where the name is whiter, we see that it brightens percept-ibly. A fine rew of trees in the park of Florence is shown in Fig. 10, the end of shown in Fig. 10, the end of the vista appearing quite as sharp and lacking in "atmosphere" as the fore-ground, owing to the penetrating power of

In Fig. 11 we have an old gate and a row of cypress trees on the road to Grasens just outside of Florence. In this cas the sky was not quite free from haze, and in consequence is not quite as dark as in the other pictures. Nevertheless even the dark green of the cypress foliage es out brighter than the sky.

I received so many letters asking for particulars regarding the method of mak--red pictures, that a fer words regarding the technique may not be out of place. They can be made with any camera provided with a ray filter (glass cell) that can be filled with a solution A saturated solution of bichromate of pot ash is put into the cell, and a strong solu tion of the aniline dye "cyanine" added until the color of the transmitted light is a very dark blood red. The scree be tested by looking at sunlit folinge against a dark blue sky, covering the head entirely with a black cloth to cut off all rays except those which come through the screen. The leaves should appear much brighter than the sky, and, if they do not, more cyanine must be added. This screen is placed in front of the lens, and an exposure of from three to five m given with an F 8 stop on a Cramer "Spec trum" plate. Ordinary ortho or trichro-matic plates will not do In England a spectrum plate is manufactured by Wra-ten & Wainwright.

These rays, which I have for conveni-ence termed infra-red rays, are not quite invisible, though they have such a feeble action on the retina as to play no part in ordinary vision, and we can see objects by them only when the eyes are carefully protected from other light. The true infra-red rays lie just beyond these d red rays, though we cannot draw any sharp line between them, for eyes vary much in sensibility in this region of the

It seems not unlikely that photographs of the planets taken by these rays will prove interesting, owing to their power of penetrating an atmosphere illuminated sunlight. If a planet is surrounded by a light-scattering atmosphere, as is the earth, we can see its surface only through a luminous haze, which would be wiped out, to a certain extent at least, if we utilized only the infra-red rays in making our observations.

It is my hope that experiments in this

direction will be made with some of the larger photographic telescopes. I espe-cially commend the case of Mars, the appearance of whose surface certainly suggests that we are viewing it through a somewhat luminous atmosphere.

It is easy to see, from the few cases I have cited, that things appear to us as they do merely from the circumstance that our eyes happen to be sensitive to a definite region of the spectrum.

laded from page 384.)

rested. In the same way he falled to appreciate the importance of the laws of heredity discovered by Gregor Mendel and later rediscovered independently by the Dutchman DeVries, the German Cor as and the Austrian Tschermak, because he did not differentiate these laws cause he did not differentiate these laws from what had been known to Darwin, and because he could not see their appli-cation to the problem of evolution of e-gains forms. He also failed to appreciate the distinction between different classes of "variations" that have been forced upon us in part through mathematical studies and in part through breeding experiments In all these cases, and some others, Wal-lane stead by the old as opposed to the new ideas.

Wheever accepts the principle of evolu-tion must recognize that it applies the hamin bloss as well as to institutions

# The Chronology of Aviation

THE Scientific American has received from Mr. Hudson Maxim and Mr. William J. Hammer, a limited number of the reprints which they have just issued of the very complete "Chronology of Avaston," originally prepared by these gentlemen for the World Almana of 1911. The data embrace the essential facts relating to aerial progress. In addition to a short historical rissumd, one finds herein tables giving altitude records, speed records, quick starting and slow-speed records, passenger carrying. English Channel and other over-water flights, cross-country flights, notable dustace and duration flights, etc. There are also statistics relating to accidents and data relative to spherical and dirigible balloons or sirships, etc. Of no small interest are the tables giving the most important flights of the Wright brothers. There are doubtless many readens of the Scientific American who are much interested in this subject and how would be glid to secure a copy of this interesting brockurts. They can do so by applying to the Aeronautic Editor of the SCIENTIFIC AMERICAN, 361 BROADWAY. NEW YORK SCIENTIFIC AMERICAN, 361 BROADWAY, NEW YORK

# **Trade Marks**

## Trade Names

Do you use a Trade Mark?
Do you own the Trade Marks you use?

You should read this booklet to obtain a definite and clear conception of Trade Mark rights

TRADE MARK is a most valuable business asset. It will pay you to know how such marks are made valuable, and why and how they are protected. The registration of trade marks is explained in this booklet, which gives a thoroughly comprehensive idea of the requirements for registration. The elements of a good trade mark are fully discussed, and many tests to determine the requisites of a desirable trade mark are given.

> The booklet is printed in two colors and is illustrated by fifty engravings

Send twenty-five cents today for a copy

MUNN & COMPANY, Solicitors of Patents Branch Office, Washington, D.C. 361 BROADWAY, NEW YORK Consider this significant fact While most of the necessaries of life have gone up, the price of telephone service, which is one of the essential factors in our commercial and social life, has moved steadily downward

Although a pound of these necessities still contains but sixteen ounces, the telephone user has been getting more and more service for less money

On the average, the people of this country pay 49% more today for food, fuel and clothing than they did in 1895 Since then, the decrease in the average rates for telephone service has been more than one-half

At the same time, the efficiency and value of the service to the subscriber has vastly increased Today he can talk to an average of five times as many persons in each ex-change as he could eighteen years ago

This is the inevitable result of the comprehensive policy of the Bell System, which brings together the as-sociated Bell companies and the communities they serve

Through the very size and efficiency of their organization they accomplish improvements and effect economies which give the greatest service at the lowest rates

Waighing Haif a Million Freight Cars
THE importance of the weighing of freight cars on
a great railway system can be readily appreciated,
as it is the basis on which charges for transportation
are assessed and is a matter in which both shipper and
courtier have the greatest concern. Nowhere is this impressed more forcibly than at one of the great railroad presson more roccupy, man at one or the great railroad centers where the freight cars are weighed and distributed to be made up into proper trains. Such a yard is that at Juniata, Pa., on the Pennsylvania Railroad, and over its track scales passes an enormous volume of traffic. In the year 1912, 488,194 cars with an aggregate weight of 23,065,750 tons were weighed at the Juniata scates, which involved freight earnings totaling the not inconsiderable sum of \$25,312,857.92.

Is it to be wondered, therefore, that the design, con-traction, and maintenance of track scales are a matter of prime importance, for an error seemingly slight ff a single weighing if continued would soon run into start-ling figures with a corresponding effect on the revenue account to the disadvantage of either the railroad, ship-per, or the stockholder.

representative of the SCIENTIFIC AMERICAN recertly witnessed the regular routine weighing at the Juniata scales and observed a periodic test. With an average of 1,507 cars weighed daily, the question of getting the cars to and on the scales, as well as weighing them with proper accuracy, becomes an interesting problem. So rapidly must the cars be moved and made up into trains that they are weighed in motion, as one by one, cut loose from a train pushed by a switching enging, they pass across a 52-foot scale rail on the platform of the scale, and then passing off by gravity they are switched to the proper classification tracks.

The estrance to the classification yard is over the

scales, which are provided in duplicate, an emergency scale the exact counterpart of the regular scale being located by its side. These scales, shown in the illustra-tion, represent the standard practice of the Pennsyl-vania Railroad and consist of a four-section lever scale fitted with suspension bearings, where the load is hung from the knife edges of the main levers and is not supersed directly upon them as in the case of older. The main levers are transverse to the principal axis of the scale and communicate their motion to the center or extension levers, by which it is transm to the fifth lever and thence to the beam, the general arrangement being that of a compound lever having the same effect as a simple lever, where a weight of 25

ng on the end of a power arm 12,000 th as long as the weight arm, would support a weight of 300,000 pounds. There is a relieving gear consisting of mechanical jucks supporting the bridge frame on which the ties and track are list, operated by a toggle joint arrangement worked by a cylinder and piston suppiled with hydraulic or air pressure and at the control of the weighmaster with a valve, so that the bridge or girders carrying the track can be relieved and supported a train, car or engine is passing without being weighed

In weighing a car it is brought to the scales in a long train amounting sometimes to one hundred cars.

At a point about 50 feet from the end of the scale
the grade begins to rise, forming whal is termed a humu in the track. As the end car reaches the upes of this hump it is uncoupled and then pushed over, and due to the descending grade it leaves the train at some what greater speed, but never more than four miles an hour, and passes across the scale platform. aster and his cierk stand in front of the beam in a bay window in the scale house and as the car gets on the track the movable police is adjusted until the beam balances, when the indicated weight is called to the cierk, who by this time has noted the number of the car and the stenciled tare or weight of the car empty painted on its side. The car then passes off the scale platform, which is at a grade of 08 per cent, and down a short plece of straight track, where it is switched as desired. If the weighmaster detects an overloaded car he pulls the cord of a whistic and the overloaded car he paint could be trimmed or exhalled, or in case the car goes so fast that the weighmaster is unable to make a rending it is sent to a track whence it can be taken over to the scale again by a switching

Steadily the cars pass over the scale, and the v master rapidly moves it along the beam after a swift glance to gain a general idea of the kind of our and, if open, its contents. Three or four cars a minute can

dight, in contents. Fare of long can a minute of the weighed by an expert weighed accurately at rest by the scale inspectors is included in a train as a surprise test for the weighmaster The scale itself is balanced daily before beginning weighing and is frequently tested master with loaded cars at rest on dit parts of the platform. As the scale is a companied lever in four sections and the weight is distributed on eight main bearings or knife edges of the main levers it is

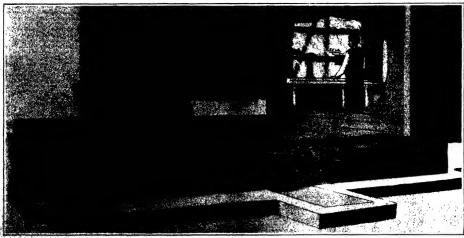

wirable to test each set with the load directly above them. The usual method is to take a to et welght eur mit low self-contidued cur of all metal construction, and pincing it successively above each set of main levers, make a series of readings. The master serie on which the test car is weighed and scaled is accurate to one part in 50,000, being adjusted and calibrated to United States standard weights

In the test witnessed by the writer, the test car was just from the master scale and its scaled weight was exactly 30,000 pounds. It was placed on the scales and the polse was moved along the beam until it balanced, swinging freely and coming to a position of rest The main pose is graduated to 1,000 pounds and the fractional or lower polse enables readings down to t0 pounds to be made. The emergency scale when test-ed was shown correct for all sections, and the same was true for the regular scale with the exception of ection which was 10 pounds out of the way , which

led the hispector to examine the appropriate levers. All the rendings being the same at each section is not necessarily guarantee to the correctness of the scale ss they are the same as the weight of the test dat ent. If all differ the adjustment must be made weight em at the virtous lovers by a process of that and error if all readings agree, but are to error by the same amount, then a shapte adjustment of the length of the fifth lever is usually sufficient to make the scale ac curate

If the scales are kept clean and properly maintained, there is little need of adjustment. The tevers of such a scale are all carefully scaled and adjusted in the shops and the parts are all interchangeable so that in case of accident, on receipt of a tetegraph order, a new part can be sent by passenger train from the scale shop

The process of scale testing is rather compilerted in its application and practice, and the technique only comes with considerable experience. The inspector goes about with his test car on a trip of from six to eight weeks testing scales and then returns to Altoon for a reweighing on the master scale, and examination of the ear, as only the most necessary repairs are allowed on the road. The bearings are responded and the car thoroughly cleaned. This work on the Pennsylvania is well done and on a few other great systems, but there has o much discussion of the shortcomings of railroad weighing that there is now in progress an investigation by the United States Government of the track scales throughout the country

Weighing a fraight our on a Pennsylvania Railroad 52-foot standard 300,000-pound capacity track scale. ear supporting the bridge frame when no weighing is in pro-

#### Water Supply of Cities Ancient and Modern

II.I. it surprise the citizens of New York, in the year 1013, to home the citizens of New York, in the year 1013, to learn, if they did not know it before, that the clizens of Imperial Rome in the year A 1 300, or thereabouts, were favored with a supply daily of somewhat over 400 galions of water per cupita, as against a supply daily of about 100 gailous per capita which is available at the present writing in this city? Manhattan and the Bronx, with a population of about 3,000,000, receive daily from the troton watershed about 300,000,000 gallons; but Imperial Rome brought in by aqueduct, chiefly from the distant bills that encircle the Campagna, over 400,000,000 gallons of water per day—and this, by the way, is four fifths of the total supply which will be led from the Catskill monutains to this city, when the new Aquednet is completed—and New York, be it remembered, in respect of its water supply, ranks high among the capital cities that are the boast of our modern clvilization.

A great constructive people were those Romans of the days of the Cosars Of pure science they knew not a little, and in provilcal science so adept were they, that the monuments of their engineering skill take rank with the noblest engineering works of the twentieth

Consider this matter of water supply. Any one who is not fully conversant with the luxurious life of that great people might readily suppose from the statis ties which we have given above, that they were afflicted with a positive mania for aqueduct building. Nothing of the kind. The Romans had a full appreciation of the value of an abundant supply of pure water, as min-letering to the health, the pastimes and the artistic delight of a city of one million souls. The Romans of Imperial days had a passion for cleanliness of body. imperial days mad a passion for cignifines or body, and the singendous public baths such as those of Trajan block-thm and Constantine, were capable of accommodating at one time from 1,800 to 3,800 bathers.

Says Prof Lanciant: "If we take 1,500 people as the average accommodation of each of the public therms and 50 as that of each of the private buths, we find that in ancient Rome at any given time, nearly 63,000 that in ancient Home at any given time, nearly 63,000 citizens could restore their strength in boths of every inture and description." The water in Rome was the property of the crown, and it was led to the private bouses by thousands of pipes, which run in every direction and under every street, and were stamped with the name of the "Concessionaire" to whom it was brought from the nearest crown-reservoir

The Roman was nothing if he was not artistle, and huge droughts were made upon the city supply for magnificent series of public fountains which graced the public squares and plazas, and were to be found casting forth the mountain waters from every point of vantage. To these must be added the thousands of foundalis which played in the gardens and courts of houses and villas of pretention, to say nothing of the supply which was necessary to maintain the beau-tiful casendes and slicut pools which formed one of the most lovely attractions of a Roman garden

To the engineer and artist allke, the most attractive feature of the water supply of Rome Is the namedness. the remains of which, in many a mile of picturesque

ruins, radiate across the desolate and solilary waste of the once fortile Campagna in the direction of the distant hills. Of these aquedacts there were eleven, or, if we include the tributaries, fourteen in all. Their individual length varied from a minimum of eleven miles to a maximum of fifty-side miles. Their total length was three hundred and fifty-nine miles, and of the street of the st this, three hundred and four miles were below ground and fifty-five miles were carried on monumental areades of massary, much of which has survived practically ct for upward of two thousand years.

The question may be asked as to why the Roman engineers built these grade-line aqueducts, bringing the water across the Campagna in costly elevated artificial river beds, when they might have built condnits that followed the undulations of the country and were sunk only a few feet below the surface. The answer is that the Romans had no cast iron or other suitable material to construct the strong piping which would have been to construct the strong piping which would make need necessary to withstand the pressures. They were acqualated with the principles of the siphon; indeed they built many notable specimens, one of which, that of Alatri, built a century and a half before the Christian era, was capable of supporting, we are told, a pres sure of 140 pounds per square inch.

Let it be understood, furthermore, that the Romans ot merely divert the water from the river beds into their aqueducts, thereby exposing the supply to contamination by the mad and silt of the river floods. On the contrary, they thoroughly understood, and practiced on a grand scale, the art of impounding the sup-ply by means of artificial dams. Thus the valley of Anio was dammed at three successive places, and at each dam was formed an artificial basin, in which the water deposited its sediment and from which it was led off, clear and pure, to the city Also, the Roman engineers understood all about tunnel construction, and in one case, between Tivoli and S Gericomio a tunnel some three miles in length was driven through

the mountain simply for the conveyance of the water.

All of which reads very much like some of those descriptions which we have published recently in these columns of the great water supply systems of Los Angeles and New York.

## Science and the Education of the Future

O the average citizen of to-day science appeals through its manifold applications. Its function appears primarily, to some perhaps wholly, utilitarian Indeed, some hold that science which does not lend to practical application is heresy.

If this be so, it appears at first sight as if science a subject of study for the young, the adolescent and the mature, could never offer more than a limited eduthe mature, could never order more man a limited con-cuttonal discipline. But this is an utterly false con-clinsion. It arises out of a misconception of the meaning underlying that much-abused word "practical". Any thing or action is "practical," which is conductive of benefit to mankind. It is a grossiy narrow view which sees benefit only in the production, transportati and barrering of merchandise—whether this be food, clothing, buildings, materials of construction or what not—and which reckons scientific pursuits as "practical" only if they can be traced forward to the mate production of such merchandise

The needs of man are not purely material. From oriai his mind has hungered for an interpretation of the phenomena of nature about him. Primitive man of the gray dawn of history, and the savage of to-day, peoples space about him with spirits and demons, to whom he ascribes the power of shaping events and destiny. To them he offers supplication to engage their favor and to appease their anger dest kind of religion, is at the same time the crudest kind of science Because it ims no obvious rela-tion to the production of merchandise, are we to remain indifferent to the development of this aspect of science? if we could do so without forfeiting all our industrial nchlevements, would we be willing to go back to that state of seientific ignorance which would lid us offer luman sacrifice to appease a rain god? Would it be "practical" to do so? Men forget that evil comes not only of ill-will, but also of ignorance, and that science brings benefits by clearing our vision \_s matter which may be of greater importance than the invention of some "practical" machine or process

Viewed in this way, science has a high humanitarian value, and its study must rank side by side with that of ancient and modern itterature. If any one still do ancient and modern itterature. If any one still do sk himself how many works of literature or fetton have had a greater influence upon modern thought in all its phases and throughout the civilized world then och-making volumes in which Darwin has laid down his classical researches and reflections upon evo

In the education of future generations we may well expect that science will be given a more and more insortant place. This not only because the young must

be prepared for the tasks by which they will later to years earn their subsistence, but also because scie strued broadly, has its le topics of the most vital interest to the life of body and topics of the most vital interest to the life of body and soul. We would not contend that it can ever take the place entirely of literature and art in its formative influence upon character; but it will be a complement to them, a complement for which there is a crying need Literature and art deal with ideals; science deals with reality. Literature and art point us a way, show us an aim, science teaches us the limitations of our resources and powers, and brings us b from the world of dreams to the world of action, from the world of purposes to that of accomplishment. It makes in "practical" in the best sense of the word, for 'practical" indeed we must be in order to translate our ideals into reality.

#### Which End of a Post Should Be Up?

T is a very common belief among farmers that a post will last longer if set in the ground the reverse of the way it grew in the tree, in other words, with the huit end up. Accordingly, one sees many posts, es-pecially end and gate posts, with the small end down. osition is that sap in a tree is always asce ing, or at least that it is easier for the sap to go up than down. Consequently, it is argued, turning a post upside down tends to prevent the rise of water, helps keep the wood dry and therefore readers it less liable As a matter of fact, sap or water can fie in either direction with equal facility and the popular notion to the contrary is incorrect.

Careful experiments on the relative durability of ost timbers have been made by the Ohio Agricultural Experiment Station and the above question was considered. One fence in particular contained 189 black locust posts, of which 86 were set with the top end up, 30 with the top end down, and 31 did not si what position they were set. At the end of 20 years 30 posts, or 10 per cent, were decayed. Of this number 15 were top up, 13 top down, and 4 undetermined. In other words one third of those set top down rotted off, as compared with only a little over one sixth of those set top up. From this and numerous other observations sion was reached "that there is no differen which end is put in the ground, except that the sound-

The decay of a past is mostly at the ground line, since it is there that the conditions as to nir and moisture are most favorable to the development of rot-causing fungl. Other things being equal, the larger the post the longer it will last. Inverting a post often means putting the small end in the ground, and where this is done the time required to rot it off is less than where the blg end is down If both ends are equally sound the larger should go in the ground. If one end is defec-tive is should be up, since the conditions above ground are many times more favorable to durability than just at or below the ground line.

## What Is Impure Air?

HE Smithsonian Institution has recently published a revolutionary memoir by Prof. Leonard hinded a revolutionary memorir by Prof. Leonard Hilli and several collaborators, eattlied "The in-fluence of the Atmosphere on Our Health and Comfort in Conflued and Crowded Places." A main purpose of the memorir is to show that the chemical quality of the air in crowded and stuffy rooms has nothing to do with its ill effects, and that, apart from the influence of infecting bacterla, the ventilation problem is essentially one of the temperature, relative humidity and movement of the air. The ordinary tests of air for carbon dioxide are declared to be worthless. The percentage of carbon dioxide in the worst ventilated room does not rise above 0.5 or, at most, I per cent, whereas the normal concentration of carbon dioxide in the lungs is from 5 to 6 per cent of an atmosphere. The writers adduce a great number of experiments and observations to prove that percentages regarded as deleterious or deadly by hygienlets are quite harfniess. They claim that it is also a follacy to assume that a diminished amount of oxygen is harmful. At noted health resorts in the Aips the barometer stands at such a height that the concentration of exygen is far less than in the most ill-ventilated room. One unfortunate result of this fallacy is that the laws regarding ventilation of mines insist on a high percentage of oxygen, and thereby increase the danger of mine explosions. Finally, the widespread belief in the presence of an organic poison in expired air is equally erroneous. The smells of crowded rooms and the like are no indication that the air is deleterious. "The deaths in the Binck Hole of Calcutta, the depression, headache, etc., in close rooms, are alike due to heat stagnation; the victims of the Black Hole died of

Canada cuts about two million cords of pulp weed annually, about half of which is exported for manu-facture in the United States.

## SCIENTIFIC AMERICAN

#### Engineering

The Bereig Lecenotive.—In our illustrated article of September 20th, 1913, describing the powerful Dissel hottometry, we omitted to state that this very interesting matchine was built by the well-known German hocomotive builders, A. Bereig, one of the oldest and largest locomotive building firms in the world.

A Thessand-feet Dry Bock for New York.—If New York on to be at a serious disideratage, as compared with the ports at Quebec and Boston, it must provide its own dry dock for the secommodation of the largest ocean liners. As noted in these columns, both of the two ports above mentioned are building dry docks capable of accommodating ships 1,000 feet in length, and this in splic of the fact that there is no prospect that ships of this size will call at any other port than New York for many years to come. We are pleased to note that the Bock Commission is planning to build a dock of this size at South Brooklyn.

Excavations as a Cause of Rarthquakes.—We note that in a contemporary journal a correspondent has made the suggestion as to the cause of the recent earthquake shocks in Panama, which is more ingenious than tis aconvincing. He draws attention to the fact that over 200,000,000 cubic yards of material has been removed from the Culebra cut and deposited elsewhere. This, he argues, involved a readjustment of weights on the surface which, taken in connection with such heavy blasts as that of forty tons of dynamic, which was used to destroy the Gambas dile, may have had some prediposing effect on the recent surfaquate shocks.

Size Pavers Economy in Ships.—In the recent James Forrest leature before the Association of Civil Engencers, Alexander Gracie gave particulars showing that increases in size is accompanied by reduction in cost of construction and operation of cargo steamers. A cargo vessed 400 feet long and weighing 3.700 tons will carry vessed 400 feet long and weighing 3.700 tons will carry vessed 400 feet long and weighing 3.700 tons will carry lead to the construction of the cargo 3000 miles on a consumption of 500 tons of coal, Each hundred tons of cargo will require only 71% tons of the 100 tons of cargo will require only 71% tons of ship and 8 tons of fuel.

Ashokan Dam Filling With Water.—The west basin of the Ashokan dam is now filling with water, which is being admitted mainly to prevent a growth of new vegetation, which if it were left dry would quickly cover the basin. Next spring the east beam will be covered with water for the same purpose. Probably no draft will be made upon the west basin supply for another year but in case of a dry season it will be possible to replenish the Croton Lake from the west basin of Ashokan. This means that by the first of next year it will be possible for residents of New York to draw water directly from the Casakill Mountains. The dam will have in the two basins a capacity of 130,000,000,000 gallons of water, sufficient to supply New York city with 500,000,000 gallons daily.

Copper Wire by Electro-depositing.—A process has been devised for the manufacture of copper wire by decir-deposition. The Braze World states that previous strength to accomplish this object have been unaucoessful. The method requires a fine copper wire as a core for making the desired product, and the additional copper is deposited on it while it moves through a tank containing the solution. The fine copper wire is made endless and passed through a regular plating solution containing sulphate of copper and a little sulphurie sold. The wire passes cover grooved rollers operated from outside while passing through the tax After leaving the tank the wire passes through a small riasing tank to remove the solution, and then goes to a reel around which it passes a number of times, returning again to the plating tank. The plating may thus be continued until the required thickness is ob-

Automatic Stop Progress.—It has been announced by the Maryland and Pennaylvania Ralitroad that the Jones automatic train stop and eab signal is to be installed on a length of seven miles on this road, and that during the coming year the road will be equipped for its use over an additional nineteen miles, making twenty-air miles on which this system will be in service. The automatic stop of the Union Switch and Signal Company is being tried on the Delsawan. Lackawanna and Westera nese Newack, N. J. This road is also installing the Federal Signal Company's audible signal for test. The New York Central and Hudson River Raliroad is testing the Induction Signal and Safety Company's system; and the New York, New Haven and Hartford will test the installation of the Union Switch and Signal Company, and snother installation is to be made for test on that road by the International Signal Company. The Fenneylvania Raliroad expects soon to test the induction apparatus of J. P. Planegen, and they have been esperimenting with the Gray-Thurber automatic stop. The Buell automatic irain stop is still under test on the Queen and Crescent Raliroad.

#### Science

The "Terra Nova," the ship of Captain Scott's Antarotic expedition, recently left Cardiff for St. John's, Newfoundland, where she is to re-engage in the whaling and sealing industry, in which she was employed until engaged for service in the Antarotic. Her figure-head has been presented to the City Council of Cardiff.

Remarkable Solar Halos were observed at various places in the central United States on November 1st and in the Atlantic States on November 2nd. In some cases (as at Springfield, Mo., on the 1st, and in southern Virginia on the 2nd) the displays were among the most highly developed combinations of halo phenomena over seen in temperate latitudes, being a ratter close reproduction of the famous "Petersburg phenomenon," seen by the astronomer Lowltz in 1700. The SCIENTYIC AMERICAN hopes to publish a more detailed account of these unusual dupplays in a future issue.

Ashmead Gray Rodgers, for twelve years supremendent of the Carborundum Company's plant at Niagara Falls, died Oetober Zitel, 1913, as the result of injuries sustained through an accident Oetober 5th. Mr. Rodgers was born in Albany, N. Y., in 1872. Previous to his coming to the Carborundum Company as superintendent, he was superintendent of the Eidly Electrical Company at Hartford, Conn. Mr. Rodgers was a member of the American Chomical Society, Engineer' Society of Now York, Chemista' Club, Niagara Cilub, University Club and Country Club of Niagara Falls and other seientific and social organizations.

An International Pharmacepoeta Office, the creation of which has recently been urged by Prof. A Tschirch, of Berne, would have at the outset for its principal task the collection of hierature relating to all the drugs and preparations in the, at present, heterogeneous national pharmacopoeta of the world. Another undertaking would be the standardization of methods of determining the strength and purity of drugs. The project of an international pharmacopoeta has often been discussed at medical and pharmaceutical meetings, but thus far without tangible results. There are now 20 national pharmacopoetas, hesides "extra" pharmacopoetas and other supplementary works; and although collectively they recognize several thousand medicanes, only about 150 are common to them all. The French "Codex" is more extensively used than any other national pharmacopoeta uside its own country. There are, however, several unofficial universal pharmacopoetas which serve to show the comparative strength of parallel preparations in different countries.

Sasweed Burning in Nerway is one of the interesting out-of-the-way industries recently described in the United States consular reports. An enormous amount of seawed is deposited on the coast by the waves in spring, and in some places the weed is out by beatmen. The-wheeled wagons are lossed with the west, slimy weed, which is taken up the beach and spread out like hay to dry. It is thon raked up in heaps and hurned. The sahes are exported to Scotland, where they are used in the manufacture of iodine, and self for 1.3 cents a pound. For the past 45 years seawed ashes have been exported requirely from Sitswaper to, Scotland to the extent of 1,500 tons and upward per annum. This industry is an important source of revonue to the pseuants who are fortunate enough to possess riparana rights, and attempts to purchase such rights from their hereditary owners rarely succeed. For a time the burner hereditary owners rarely succeed. For a time the burner of seawed was prohibited through the influence of the fishermen, who declared that this practice drove the fish way from the coast.

Tunseling the English Channel has been tailed of for generations, and from time to time the sehome seems of the control of the

#### Aeronautics

A Royal Aeronaut.—Archduke Josef Ferdinaud, of Austria, has justified his predicate of "Imperial and Royal Highness" by making 100 balloon voyages.

The Psychology of Air Scouting .- In actual war, both in Tripoli and in the Balkans, aviation accidents were conspicuously few, and this despite the fact that winds were generally high in Tripoli, and the season of the year id the weather extremely unfavorable in the Balkana It is a matter of considerable psychological interest to note that the danger from an enemy's fire so stimulates vigilance that norves are tense with exertion and the mind is relieved from dwelling upon the ordinary dangers of is relieved from dwelling upon me orientary sangests or keeping an aeroplane on an even keel and meeting every gust. In other words, scouting in actual warfare seems to be a splendid cure for nervousness. The aviator must fly with the assurance of a bird, and he does so for fear of the enemy's rifle fire. A striking instance of this psychological phenomenon is the fate of Dr. Jules Constantin, a French aviator in the Bulgarian service. He was mortally wounded in the air during a flight above Tchatalia, as we recorded at the time, but managed to land safely only to die before anyono could reach him. His dead hand still grasped the steering lever, a bullet-hole was in his breast. The feeling of detachment from the ground at 3,500 feet probably dispels intense fear nificant that, because everything is hea lt 18 se everything is heard so clearly in the air, even to such trivial noises as the barking of dogs and the cackling of hens, the roar of battle is exaggerated and seems more intense and tremendous than it really is

Recent Aeroplane Patents.-A patent, No. 1,074,007, has been issued to Frederic Mylius of Atlanta, for an aeroplane which has a transverse carrier plane whose upper surface is concave, and rearrandly con-verging guide planes which are secured at their forward ends to the carrier plane and have their upper sur-face converted educations. concaved adjacent their forward ends and vexed adjacent their roar ends. In a patent, No. 1,074,-063, to Harry A Orne of Wesley Heights, D. C. is shown a vertical steering plane with a curved slot and anown a vertice ascerning plane shotted to receive the verti-cal plane and movable from side to side, a rib of the horizontal plane working in the curved slot of the steering plane. Ralph P. Fox of Fort Hancock, N. J., has secured a patent, No. 1,073,977, for a safety support for flying machines in which is provided a main support-ing surface, an auxiliary balancing and supporting surface in front, rear and at opposite sides of the machine and beyond the main supporting surface, the balancing surfaces being of circular form in plan and elliptical form in vertical section and presenting opposed upper and lower convex resisting surfaces. Cleve T Shaffer of San Francisco, Cal., in a patent, No 1,071,101, provides an apparatus in which an aeroplane is supported and propelled along a track and is flexibly connected with the track, means being provided for controlling the flexible connections for regulating the universal inovement of the aeroplane relative to the supporting track.

Armored Acroplanes in Franco.—It appears that the German war department took the lead in protecting acroplanes by armor plating, and after this the idea was taken up in France, where several armored flyers were to be seen at the last Prans show. However, the French army did not go extensively into the matter before attention was called to it by two events, one bong the experiments made at the Touloin arsenal in firing upon acroplanes has tyear, and the second the results of the first war in the Balkans. It was then resognized that all acroplanes were vulnerable when flying below 4,000 feet, and with the present system of observing, a machine needs to fly as low as 2,000 to 2,500 tot in order to see the state of affairs on the ground. It would thus be exposed to artillery and infantly fire. Two solutions were presented for protecting acrophones, first to armor plate for the men, mutor and devices, or only to protect the acroplane guiss and in this case keep the flight very high so as to prevent being hit. Here, the observer would be at full length and observe hy acts of lenses. The French army decaded to adopt the ties doubton, that is, good provent being hit. Here, the observer would be at full length and observe high the way armored accoplance will be made up of the following types of acroplane: First, armored single-place flyers for articlery and eavalry secuting and for short secuting trips at the speed of 70 miles an hour. Second, the Eta-Major will make use of two-place scutting acroplanes, also armored, and used for 60 miles at hour speeds. The third kind is an armored two-place with untralleuses and automate genes, intended for pursuing the ensemble of 50 miles and hour, designed for speeds of 70 miles and hour speeds of 60 miles and hour, designed for speeds work.

# A Radical Improvement in Cabling

## Eliminating the Siphon Recorder

By Herbert T. Wade

TellaT improved methods of working submarine clouds are desirable may be appreciated from a statement authoritatively made that the number of cable messures sent throughout the world practically doubles itself every ten years, and the fact that recent changes of policy whereby deferred and other messages or cable letters are taken at reduced rates, are naturally leading to an increased use of the submarine telegraph in definition to the purely normal growth. A new method has been developed by which Morae signals may be sent through long submarine cables with some approach to the facility edgoed in the transmission of the familiar dots and dashes on overland circular. This new system promises to produce many radical changes in handling the ever-crowing traffic now car-

ried over the catalon of the world.

By the new method re-transmission at the cable or land ends is obviated, the shipon recorder used since the days of Lord Kelvin gives place to an ordinary Morse recorder or sounder, with a corresponding increase of accuracy in transmission and saving of line in deciphering the received message, and a number of short cables can be linked up for direct working, withe long

land lines can be connected directly to a cable system, all messages being automatically relayed to practically any distance. The seeding of signals over lost cables can be effected by an ordinary teiegrapher with a signal Morse key lines of the double key of manual cable working, while a Wheatstone or other aimiliar automatic transmitter may be introduced in case increased speed is desired. Consequently the new method establess uniformity of operation between land and submarthe lines and makes possible the fullest and most rapid interchange of traffic

The invention resulting in these innovations came as the result of many years of experimentation on the part of John (fort of Hove, Smeez, England, chief electrician and consulting endoner of the Commercial Cable Company. In addition to daily use between London and New York special demonstrations have been made of direct communication between San Francisco and London, as well as between the latter city and Montreat, Toronto, Winnipez, Victoria, and Bumfield, P., C., on the count of Vancouver. Although the new method is one of extrome simplicity and requires no other piparatios or instruments than may be found at

any cable terminal or testing station, it affords the solution of a problem that has held the attention of cable electricians for many years.

Hitherto even using the most sensitive instruments in has not been possible with a long cable so to interrept the electric current as to form signal impulses or greater or less length such as the dash and the det, but it has been found necessary to reverse the current and distinguish the two eleneats of the signals by its direction. Thus in ordinary cable working substace, indicated in the Morse code by a dot, would be signified by a + impulse, while t, represented by a dash, would be a — impulse, the galvamenter or siphon recorder at the receiving station indicating such impulses by an appropriate deflection of mirror or moving cell in one direction or the other. This of course would be in response to the signals of the senging operator made by depressing one or the other. The of course of the transmitting key, depending whether he wished to Join the positive pole of the battery to the entile and the negative to the earth or vice evers.

As in the case of the land telegraph it is possible to send two messages in opposite directions over a sub-

signal. But at the opposite end of the line where the agnal. But at the opposite end of the line where the same arrangement prevails an electrical impulse or sig-nal received will have the effect of adding to or sub-tracting from the potential on the cable side of the bridge and consequently act to destroy the balance of potential, causing the moving coll of the galvanometer or siphon recorder to be deflected appropriately. The the currents after each signal and then transform the resulting impulses into regular Morse. Various sug-gestions have been made for mechanical and other devices to effect this desired reversal of current in each successive impulse, but it has remained for Mr Gott to work out the problem practically and electrically so that an ordinary Morse operator can send the conven-

## SCIENTIFIC AMERICAN

tional signals with the usual type of key, with the result that so far as the sender is concerned there are substituted the impulse signals by intervals of dots and dashes, while at the same time all of the advantages involved in the reversal of current for each successive stream.

In its essence Mr. Gott's method is exceedingly sim ple. The change in direction of the current is offered after each signal by the use of a polarized relay through which the cable is discharged and the path of the current reversed for the next sending signal. polarized relay may be of any type of suitable sensi tiveness and resistance such as is employed on land thues. It consists of a permanent horseshoe magnet with one of its poles divided and formed into pole pieces around which are fitted colls of fine copper wire through which the current may pass. Between these pole pieces is poised a soft iron needle or tongue, free to move, but normally held at rest in a neutral position by the fact that it is attracted equally by both Now, if a current passes through the coils it will strengthen the magnetism in one of the Iwo pole pieces, depending of course upon the direction of its flow, causing the arm or tongue to be attracted to one side or the other. In so moving it comes into contact with one or the other of two stops and completes a local circuit where the direction of the current depends upon the direction of the current flowing through the colls of the relay. The application of the polarized relay in the Gott method will appear on reference to the ac conpanying diagram (Fig. 2), which shows a cable ar-ranged for dupiex working. The cable itself is shown at a and the balaucing or nertificial cable having the same resistance and expucity required in duplex work ing is placed at b with its unconnected end grounded Between the real and the artificial cubic is inserted the receiving instrument 1', and then after connecting with the condensers at c and c' the circuits unite at c, where the transmitting key d is placed. So far there is no variation from ordinary duplex working. The key however is arranged so as to connect  $\epsilon$  either with g, as when at rest or normal, or when depressed at f with f, as when sending a signal. Both of these connections as when sending a signal. lead to the polarized relay h and by tracing them out on the diagram the action will be apparent. Proon the diagram the section will be alpharent. Pressing down the key at f to make a dot or a dash the cable is put late connection with j, which is turn is connected with the movable torque h, and through it with one of the stope K, each of which is connected with an opposite pole of the spill batter; at I and T with an earli connection at M Consequently depressing the key would charge the cable by connecting the conders with the battery, and the polarity of the charge of current would depend upon which of the stops at h'the movable tongue h" was in contact with. Now permitting the key to return to its normal position establishing contact at  $\sigma$  causes the cable to discharge through the polarized relay and the current flowing through the culls would send the moving tongue or arm from one stop ut h' to the opposite so that where the + pole of the battery had been connected to the line, at the time of sending the next impulse or signal it at the time of sending the lest mappins or signal it would be the — pole. Thus every time the key is depressed the cuble and condensor are charged with the discharge of the line between successive unit inpulse signals goes on continuously, no two successive signals being of the same polarity. As the energy of the discharge from the cable is considerable, the resistance of the coils of the polarized relay does not figure and the cable is restored to a neutral condition so that good and repid signaling is possible

A modification in the sending method involves the ase of a transformer in connection with the polarized relay as shown in a second diagram (Fig. 3) and in the photograph of the operator and instruments. In the diagram the condenser and cubic are enritled directly at fy after each signal and while the key be open. A split battery is provided as before which is earthed at # through the primary cell P of the transformer. The coils of the polarized relay are in connection with the secondary of the transformer 8 and the centure point of the key f is connected through the movible tongue & with the stops that in turn are connected with the split or double battery. The function of the transformer is to induce in the secondary cell, which is connected with the coils of the relay, a current that will send the tongue over against the opposite stop so that when the key is next depressed the direction of the battery current to the line will be reversed from that of the previous impulse or stomal. These reversals take back in the relay is equipare sequence so that no two successive currents sent are of the same polarity. An advantage claimed for this method is that on making contact with the key to charge the called the battery content.

key the tongue of the relay of a land line is very simple on is shown in the diagram (Fig. 4), where T takes the place of the key of Automatic transmission is also possible, using the punched paper and the familiar Whealstone transmitter employed in high speed teiggraphs. The Wheatstone transmitter takes the place of the key, the two upper contacts of the vibrating contact arms being used for this purpose and the revent proburtsed relay embryed as with the hand key.

To understand the receiving arstem the diagram (Fig. 5) should be examined in connection with that of the sending station. At V, where the sliphon recorder continerily is placed, a similar instrument, but one provised with a contact making tongue attached to the moving ceil, is used. This tongue or arm makes contact with either v or v', depending upon the pointify of the current coming through the cable. These plates in the instrument are insuitated at v, but are connected at W and are in circuit with the local battery r, and a sounder or recorder at Z, which however may be a reisy or any desdred interment. While the contact place at V will move from one side to the other depending upon the polarity of the arriving current, the effect on the local circuit will be the same in either case and the dot or dash is sounded or recorded just as if it were but a simple break and make of the circuit as in Ordany Morse working.

Now from this outline description it will be evident that these various arrangement can be combined practically indefinitely. Relays from land lines can be used to work sections of ocean cables, and the signals from one section may be transmitted to the next and finity to a relay working a land system of practically any length. Thus when the operator at San Francisco was communicating direct with London. his message was

Simple method of laying out a pentagram.

relayed across the United States by nine relays work ing over us many sections into the cable office in New receiving relay automatically gave message to the Goit arrangement and the electrical sigmessage to the doil arrangement and the electrical sig-mal impulses were sent on their 1,000 mile journey to Canso, Nova Scotla, there to be received and auto-matically sent on the long section of 2,565 miles across the Atlantic to Weston Super Mare, England, where a similar retransmission through 146 miles of subter-ranean line took place to London and the message from the Pacific Coast was heard in that city with the familiar click as If it were but from Manch Is a point has now been reached where no fimit can be upon the interchange of traffic up to the capacity of the individual lines and cables making up a system Scientifically the problem of Morse signals and reversed currents has been solved, but problems of traffic remain A cable represents a costly investment and its use must be planned for a maximum of efficiency and a minimum of idleness whether it be for tack of bud ness or waiting time to connect directly two distant The new method affords much greater facility of working, and while it will not phenomenally i the actual speed of transmission yet it will, as in fact the section speed of transmission yet it will, as in nect it has done, make submarine ielegraphy more effective, accurate and uniform. Indeed with this and other inventions and instruments it may be said that cable working to-day is in a transitional period toward even greater efficiency, and that the day of the abandonm of the submarine telegraph with its lines of copper, guttapercha and steel armor for radio-com

#### International Exposition of Safety and Sanitation

R AILROADS covering nearly a billion locomotive miles are in the competition for the first award of the E II. Harriman Memorial Medais, which will be made at the First International Expedition of Safety and Sanitation, to be held in New York city, December 11th to 20th, under the auspices of the American Museum of Safety.

The Jury of Award consists of Jane Addams, Vincent Astor, Mrs. August Belmont, Surgeon-Genéral Emperilles, Mache I. Boardman, George B. Cortelyou, John H. Finley, Irving Fisher, Elbert H. Gary, Prof. F. R. Hutton, Joseph Johnson, J. B. McCall, president of the National Electric Light Association; Dr. William E. Nichols, John H. Patterson, F. E. Rogers, B. B. Thayer, Littlen Wald, W. T. Wilson.

The Safety Exposition will be the occasion of the annual meeting and dinner of the American Museum of Safety which will be held at the Waldorf-Astoria on the evening of December 12th. One of the speakers will be President Aribur T. Hadley of Yale. All of the awards will be made on this occasion, including the Harriman Memorial Mednis, the Safety Exposition Mednis, and the annual medias of the American Museum of Safety, consisting of the Schretten Museum of Safety, consisting of the Schretten American, the Travelers, the Semmen and Rathenau Mednis.

#### To Strike the Pentagram By John P. Robinson

W HILE there are various methods of striking the five-point star, the following one worked out partitle by by chance by the writer, while demonstrating certain attributes of Encilis' forty-seventh problem, is very simple and direct. Moreover, it offers an easy method of striking the star on a large scale, say for laying out a lawn bed, or other and larger applications, decorating, etc. It offers interesting suggestions as to the 3, 4, 5, and 8 reintions, as one will agree upon working it out. All that is needed is a measuring sitch, struck into 3, 4, 5, and 8 spaces. Try it at first with a common inched ruler.

Frave the base line, 1—2, eight inclew long, marking off the center at four inches. At the center, ertike a perpendicular time of six inches, three above, three ledow the horizontal line. You now have a cross, two arms having four-lineh, and two three-lineh dimensions. Call the top of the perpendicular No. 5, and the best of the control of the perpendicular No. 5, and the best of the control of the perpendicular No. 6.

Now, according to Euclid's problem, if 7—2 is four tuches, and 7—3 three inches, 2—3 would be five inches, which is found to be the case. But the base line 1—2 is going to form the "peaks" of our five-point star, and these are just eight inches aparl 80 now put your ruler on 2 and let its five-inch mark

So now put your ruler on 2 and let its five-inch marks plast touch No. 3, draw a stratch line, seeinning at 2, 2 passing the polut 3, and continue three inches more: this will make the 1the just eight inches long. Now place ruler out 1 and 3, and draw an eight-inch line also. Call the terminals of these more lines, 5 and 5 praw a set of the 1 place from 5 to 4, one from 4 to 6, and you have the star.

The simplicity of this method should commend itself to those wishing to strike large star diagrams. We two common chalk times for bose and perpendicular, a rough pole as a measuring unit, you can easily strike a star inving its base of two pulms eight times as long as the pole. The method is direct, much mure so than striking from five points within a circle, especially when there is no easy method of quickly obtaining the 72-degree spatching of the circle except by trying five times arround.

## Is the Whale Disappearing?

This fact that whate is disappearing it pointed to ut by M. Ed. Perrier, head of the Paris Natural Instory Misseum Several species will probably soon be tost on account of the very active hunting being carried on a present. No less than thirty Notwegtan companies are engaged in this work off the western coast of Arfica, and on the castern coast in the Mozambipur region. The danger is as great from English enterprises. This account of the future extinction of the whale led the Anderbry to pass resolutions recommending the interest of the government in the matter and cailing for an international commission.

## The Current Supplement

THIS week's issue of the Schettic Astraca Schetting and the Schetting complete tables of the arrowed ships of our Navy, showing their principal dimension, dute of hunch, number of rgms, speed, etc. The tables are prefaced by some introductory remarks, which we owe to the pen of a naval expert.—Prof. Charles L. Paranon, Chief of the Division of Mineral Technology, Bureau of Mines, reports in detail on the radium resources of this country, which seems destined to become one of the principal producers of that ultra-practions material.—John J. 16s gives a brief description of the latest military type Borel monopian.—Dr. Geoffrey Martin contributes an article on the production of prycohoric alloys used in gas, eigarette lighters, etc.—Irving C. Allen writes on "Hency Oli & Fuel for Internal Combustion Engines".—P. S. Millar, in an article on "Some buston Engines".—P. S. Millar, in an article on "Some buston Engines".—P. S. Millar, in an article on "Some buston Engines".—P. S. Millar, in an article demonstrations of lighting effects produced different sources under different sources under different conventions.

#### The Abuse of Carbon Copies To the Editor of the SCIENTIFIC AMERICAN:

Not the least of the advantages which the modern nethod of typewriting offers over the old process of writing by hand, is the great case with which a num-ber of exact copies of the matter can be prepared at one operation. No one could possibly find fault with the common practice of this method, so long as it is not abused. One or two carbou copies can, with proper precautions, be made almost as legible as the original. Furthermore, if an additional number of copies are filed for one's own use in an emergency, in many cases the requirement of ready legibility may legitimately be d to fall somewhat into the background. But allowed to fall somewhat into the neekground. But the practice, unfortunately somewhat widespread, of sending out in the regular course of business, docu-ments the reading of which is an excessively severe task on the eyes, cannot be too strongly condemued. Will you permit me, through your columns, to put on record a protest against this practice? There is an easy remedy against it. Return all such defective carbons to the sender with the request for a readable copy. A glance at the matter received will suffice to determine whether the importance of the document is such as to induce the recipient to make an exception to his rule, but I venture to predict that the occasion will not frequently arise A person who has anything of value to municate will in most cases have the judgment and good taste to present it in respectable garb.

S. M. Gainte (We take pleasure in publishing Mr. Gridley's letter As editors, we have only too frequent occasion to make observations similar to his, and we can fully indorse him on every point.—Entros.]

#### An Aerial Maneuver

To the Editor of the Scientific American

The San Fernando Vailey is a level plain, oblong in shape, perhaps 10 miles wide by 30 miles from southeast to northwest, situated near Los Augele from southeast to northwest, situated near Los Auscies and almost surrounded by high hills on the south and the Sierra Madre Mountains on the north, inck of which is the Mojave desert. A peculiarity of this country is the almost total absence of what are known as turkey bursards. On September 50th heat, at about 4 P. M., I noticed an immeuse flock of buzzarde circling. around over the extreme south side of the valley, near the Cahmuga Pass, which leads into the city. contained probably five hundred birds, and most of them, if not all, were turning from right to left and mounting higher at every round. As the column mounted higher it was continually augmented by hirds coming from every direction, singly, in pairs, and flocks ing from every direction, one shape, in pairs, and noces of various numbers to perhaps twenty, which promptly took their places in the column, which finally reached to a considerable height, probably three thousand feet. As soon as this height was attained the birds "volplaned" to the southwest, the nearest point to the coast, about 20 miles. This performance continued until the last bird was sailing away toward the sea. The above out did not last longer than 30 minutes, but there were thousands of birds that left in the flight. They were probably migrating, but the query is. Where did they come from, and how did they know the date and place to meet and make the start?

Lankesshire, Cal.

A Mr. Frank Young was present and saw the above.

and will affect to the truth of the statemer

## A Plea for the Fox and His Fellows

To the Editor of the Scientific American:

You have been exceedingly generous in granting space for reference to the need of a humane trap. All lovers of animals must appreciate this. The Massachusetts Society for the Prevention of Cruelty to Ahimals certainly does. We have been doing what we could, and some success, to secure legislation against the tashioned steel trap, with its possibilities of torture for the victim caught. The question has many sides to it, as some of your correspondents have discovered.

as some or your correspondents nave discovered.

For the benefit of one of them I would like to call
attention to John F. Draughon's "Fur Searing Animals
the Farupar's Friends." He says, in substance, the
United States Department of Agriculture states that
eighty, million dollars' worth of damage is done each
year to crops and fruit and forest trees by field mice, ground squirrels, moles, pocket gophers, and grasshop-pers, and that these pests constitute from eighty to ninety per cent of the food of foxes and other fur-bearimals, such as wolves, lynzes, badgers, races, skunks, minks, wessels, and shrews.

warning, therefore, is given by the Department that unless a check is put upon the killing of foxes, sknuks, is, and the like, the farmer will continually find it harder to reap the reward of his toll. Even if ocsionally a chicken is taken from the hen-yard by for or skunk, the assurance is given that the farmer might better far pay this toll than kill the robber. Mr. Draughon is regarded in Tennessee as an authority on d in Tennessee as an anthority on Francis H. Rowley, President,

Boston, Mass.

## The Ten Most Needed Inventions

To the Editor of the SCIENTIFIC AMERICAN:

A correspondent asks, What are the ten most needed inventions? Allow me to suggest the ten following: 1. A practical substitute for lead for use in secondary or so-called storage batteries. 2 Automatic stoking device, which will do the work as well as human hands 3. Substitute for the wasteful wooden tie used on rull-4. Reduction gear and reversing device steam turbines. 5. A commercially practical method of fixing atmospheric nitrogen. 6. Some method of suspension or spring wheel which will do away with the necessity of using pneumatic tires on motor necessity or using pneumatic tires on motor cars. 7. A substitute for gasolino for use in internal combustion engines, 8. An automatic stabilizer for aeropianes, 9. Method for delivering the energy in coal directly as electricity with the interposition of steam engine and to. 10. The discovery of the secret of the firefly dyna and its application to the production of artificiat light.

#### The Most Needed Inventions

To the Editor of the SCIENTIFIC AMERICAN Noting a recent inquiry in your columns the writer suggests that an attempt to limit the most needed inventions to ten would appear to be absurd. One can think of more than that many offnand, as for instance:

- 1. An electric light as efficient as the molor A storage battery as cheap as dry cells, light, efficient, and foolproof.
- A new product which will utilize or require the use of vast quantities of chlorine to advantage
- 4. A wireless telephone which will cost no more and use no more power than the simple sets now used on
- short inter-communicating lines.
  5. A glass or substitute therefor which will withstand strains without breaking, without losing the usual transparency.
- 6. An economical crude oil engine light enough and adapted for automobiles and similar service
  7. Cheap substitutes for leather and rubber which
- have the properties of the natural material and which can be n
- can be mude on a large scale at low cost.

  8 A lifeboat which will not sink or capsize and which can be lanuched safely in a heavy sea 9 Means to prevent railroad wrecks which will,
- within human error, prevent such wrecks entirely 10. Real cures for consumution and caucer.
- 11. A detector for radio communication which with out sacrificing the sensitiveness, rigidity, and practicability of present long distance types, will still be of itself, or in conjunction with a positive rapid relay mechanism, capable of automatically transmitting the received energy into lond or visible signals under all

conditions met in practice.

And so the list might be continued. Many of the items are of course already receiving attention with en-couraging results; certainly we shall see at least some of these problems solved and perfected. It would be ng to note the individual opinions of s hundred readers engaged in the various arts and indus tries. Then, perhaps, it may please at the ten most urgent. Public PHILIP E. EDELMAN.

## Just What is a Cyclecar?

To the Editor of the SCHENTIFIC AMERICAN:

This is in reference to the article on Cyclecars, appearing on page 205 of your issue of October 4th. After reading the statements contained in this article in regard to the American cyclecar, the question naturally gard to the American exceeding the method market, "Where does the cyclocar stop, and the automobile begin?" In other words, what is the distinction? Why is the vehicle shown, for instance, at the er left hand corner of the above page any more upper sett finant corner of the move page any more a "development of the motorcycle" than it is a development of the automobile? It would be a good idea if you would publish a definition of "cyclecar" for the mefit of your reader Washington, D. C.

[Abroad, where cyclecars first saw the light of day, [Abroad, where cycleaers first saw the light of day, they were a development of the motorcycle, or rather from the motorcycle; they consisted, and still largely consist, essentially of motorcycle parts, and for a long time the Royal Automobile Club was hard put to 1 to find a class in which to place them. At leasth it was determined by the International Federation of Motorcycle Clubs to place cycloaers in two classes, both

ses to consist of vehicles having either three or four wheels and for one or two passengers. The targer class includes vehicles with a maximum weight of 784 pounds and a maximum piston displacement of 1,100 cubic centimeters, the tires to mensore 2 % luches in section; the smaller class to have a minimum weight of 330 pounds and a maximum weight of 660 pounds with a maximum piston displacement of 750 cubic centimeters, with three measuring 2.1/16 linches in section, att vehicles must be equipped with a clutch and change speed gear. Hence, the foreign cyclecar conforms largety to these simple specifications. In America, manufacturers of so-called evelours have given no intimution of being bound by even these figures, and we find vehicles exceeding both weight and engine capacity unceremoidonsity termed cyclecars despite the fact that the so for as the L. F. M. C. definition is concerned at least—they not the 1.F. at a meanitude of concerning at easts—they are little more than small cellflows of targe automobiles, many of the attributes of which they retule. Strictly speaking, they are not extensive as was made plain in the article to which you refer, they are developments of the automobile rather than of the motorcycle. gh the fact remains that their bispiration spring from the two-wheeled vehicle --- Epitor !

## Expert Report on the Last Zeppelin Disaster

In the issue of November 1st of the Scientific American the writer discussed the "Lessons of the Zeppelin Airship '1, 11'" — It is interesting to compare with the observations then made, the expert report of Dr Eck ener on the probable cause of the explosion of the lilflated craft. From this report the following excerpts are

"There can be no doubt that at the moment of catching fire the cruft was practically enveloped in a layer of explosive anti-hydrogen mixture and that these gases were ignited in the forward engine on to a spark of the like In the engine our there ought to be no possibility of any explosive mixture of gases being present

"Ir Eckener further concludes that the entostrophe of the "L 11" was brought on by the peculiarities of the construction of the vessel. In point of fact the new type of the "L. II" was the subject of serious disenssions between Count Zeppelln and his experts, as well as those of the may, and it may be freely stated that Count Zeppelin ilid not regard this type as helug quite as safe as his earlier constructions, and set out moon the building of the ship with a certain amount of esitation, nithough the design of the ship was in other respects very excellent

respects very excellent
"Wherein lay the new features of the "L 11" as compared with the older types? Principally in respect to
three points." A gaingway was placed hislds the ship,
the cars were drawn up close to the balbon, and the forward engine car carrying two motors was provided with a large wind screen to protect the passengers from the rush of air. The question is. Which of these three factors caused the explosive gas mixture to enter into the engine car?

"As regards the first point, placing the gaugents within the balloon, this in itself is not a serious matter It is true that a temporary accumulation of gas at the top of the gangway may occur at the time of blowing off gas, but gas so escribing would not thereby be brought

"More danger must be seen in the second feature, the closer approximation of the cur to the body of the

"But unquestionably the most fatal error to the con struction was the provision of the screeps. A dend struction was the provision of the screens A decid squee is formed beidnd these, in which air and hydrogen may accumulate. The entastrophe of the "L tt" can therefore be explained only as follows.

"The alrelity tiding rapidly gave off a large quantity

of rag. An explosive mixture was drawn into the for ward engine car and was ignifed by the flame of the carbureter or some other shullin cause Once this ource of danger is realized, the remedy for it is not far to seek. Proviston must once more be made as on former occasions for good ventilation over the en-regardless of the comfort of the passengers. If t If this is properly attended to, future air-ships will be as safe from explosion as former models. Perhaps it will be as well to go a step further and to cause the escaping gases to leave the balloon at a point where they are not dangerous to If'

If the realer will refer back to article noted above, he will find that in att essentials this agrees with the expert upinton here quoted

## A Good Furniture Polish

A GOOD furniture polish, whilch is black and which will remain soft in the container, is made as follows: Three ounces of wax, two ounces of pearlash and six ounces of water are heated together, and when thoroughly mixed add four ounces of bolled oil and five ounces of turpentine. This should be poured in wide mouth containers, where it will keep indefinitely.

# Electric Signal Method of Firing Navy Boilers

## Automatic Indicator Tells When to Stoke the Furnaces and Amount of the Charge

THE Nichausse electrical signal method for furnace firing has proved such a success that the French navy is now adopting it as standard upon the buttle ships of the fleet which are operating by steam turbines, and it is also coming tuto use upon many oth

In the old method ing the overseer in the fur nace-room calls out the time and order for stoking the furnices, and this is likely to make him neglect other duties such as ob-serving the water level, cont conveying, ush empty

In the simplest form of the electrical apparatus the operation is as follows. An automatic signal sender is placed at the control hench of the engine-room and at the chief engineer's hand This officer pos-

number of furnace charges per hour neces the different rates of combination per square foot of grate surface, and in consequence the different rates of steam production. For instance, should be need 15 combustion, he sets the automatic signal sender for this figure, so that signals are sent accordingly to the fur-incernom. The signal sender 1 is a simple device currying a clockwork driven shaft with sets of disk-Each disk has two projecting coms which work mon lever arms on the base and the com driver its lever arm so as to make an electric contact, there being thus two electric contacts per revolution of

a disk. Our engraving shows four such disks, also an outer cam disk for ringing un electric hell. The engineer sets the speed by turning a numbered disk to 15 or other number of charges per hour which acts on the mechanism the apparatus gives the needed signals to all four furnaces at the proper rate, without any more attention, by the use of a luminous indicular board. The latter is placed in the furnace quarters and consists of four luminous panels C mounted in an iron box, each panel being connected by wires to one of the disks of the sender.
As disk No. 2 revolves, for instance, it makes an electric contact so us to light up the lamps be

hind panel No 2, thus indicating "Clurge 5 shovelfuls ning panet No 2, times indicating "timings of smoothus-into furnases No 2," and the electric bell rings at the same time. In the same way panels Nos 3, 4, etc., are operated to turn, and time all four furnaces are stoked in the proper order. The number of slowel-tuls per charge is set once for all to 4, 5, 6, etc., by turning a button placed beside the number on luminous board, and should there be differences in the grate surfaces these can be compensated in this way. Pilot lamps in the engineer's post enable him to see that all is working properly The signal sender is all Inclosed and can be set at once from the outside to

any rate that the engineer may require for a given period of time, simply by turning the numbered disk so us to accelerate or diminist the rate of stoking.

since the use of multi-tubu int bollers, which are very scusifive to sudden changes in firing, the Navy Department recognized the necessity of using a methodical stoking as besides giving a better steld. It partly preven the volumes of smoke which show the presence of the versel to the enemy. On board the "Ernesi Renan," which possesses 42 hollers and 8 stoking passages, the old method of conducting the furnace firing by clock, which was the only means then used, became almost useless fact, the chief engineer in the engine-room could only com-municate by speaking tu be with the furnace functors, and this resulted in errors of

transmission of the number of charges to be adopted and hence much irregularity in operation. Then the Nichusse system was put in, and it rendered such good service that the personnel on board pronounced unanimously in its favor, so that it was retained in this ves-

A-The signal sender. set and soon afterward installed also upon the "Patrie

and at a later date upon other battleships. Each of the furnace passages is provided with one luminous indicator, and the engineer can turn his disk so as to instantity themse the second of the contraction. instantly change the rate of combustion of all the fursides, the system allowed of eliminating 24 stokers, was shown during the first tests, and moreover the greater regularity of combustion resulted in a lessenline of contamplion, so that now this was only 707

sion of sufely-valve lifting almost entirely, of bringing

C-Luminous indicator in the furnace-re-

over of water, and of flames from the smokestack which are an inevitable consequence of bad firing, were noticed in this case. Upon the appearance of 23,000-ton battleships it was feared for a time that the maneuvers would not be as rapidly carried out with steam turbines as upon engine equipped vessels, and a remedy was sought in making

equipped vessels, and a remeay was sought in making in closer connection between bullers and turbines than before, especially as concerns the reverse drive. This led to the use of a somewhat more elaborate form of apparatus which we filustrate, the object being to send more complete signals to the furnace quarters. The same signal sequence is once an bestore, and to it is access an "order transmitter" B with three handles working upon numbers so as to give the following indications upon luminous panels; first the indications as to speed of the engines (five signals), "speed to be accelerated,"
"stop," "forward," "re

verse," and "speed to be diminished;" second, combustion figures showing the tion rate per sq meter of grate surface and per hour from 40 up to 180 kilogrammes if need be; third, the number of shovelfuls for the furusce charging. This will be clearly seen upon the two luminous boards, the first top range the five spe als just named, while the lower range shows the bustion figures 40 to An electric bell is also

used. Above 80 the num-

ber is obtained by using two figures and adding them, for simplicity. The second luminous board E is a modification of the first-mentioned one, and indicates "charge furnace Nos. I, II, etc., with 3, 4, 5 or 6 shovelfuls," as the case may be. All these indications are indispensable, for it is not enough to use the first-mentioned device alone for the furnace firing in this latter case, for even though the stokers obey the firing signals, they only perceive after a certain time that the firing rate is becoming more rapid or slowing up, and it is preferable to call their attention at once to changes which are being made in the firing rates, so that from the

ilirst moment they can look after the fires and vary the draught either by working at the ash pit or by attending to blowers or air compressors. The chlof engine therefore operates the rate The calor engineer therefore operates the rate disk of the signal sender and also the three handles of the second device or "order transmit-ter." The three dials here correspond respectively to combustion figures (40 to 80, etc.); second speed figures, also stop or reverse; third, number of shovelfuls per furnace charge. As to the last, it is seen that the engineer can vary the number of shovelfuls at any time, while in the last, it is seen that the engineer can vary the

the three mandes of the order transmitter, the first two work together with the first luminous board, while the third (shovelfuls) works upon the lower range of figures in the second board (8, 4, 5, 6). The clockwork signal senders work with the upper range of the second board to show the numbers for the furnaces (I, II, etc.), and to ring the electric bell, as before. With the present simple and effective apparatus no false maneuver can be made, and each change in operating the vessel is made to give the corresponding change in the whole of the furnace quarters, instantly showing what is to be done so that the new conditions are met, without abrupt changes. At present the personnel has become so accustomed to the

would now be welcomed. To sum up, the apparatus gives the chief engineer ractical means for regulating the furnace firing in second with the speed of the engines; easy to the stokers on account cations it gives; the engineer the clock to regulate the fir ing and can give best atten-tion to the other points. The ciable economy in combi and gives greater regularity in the running of the engines. Furnace firing takes place under better conditions of fuel burning and this avoids some of the well known draw-backs of the former method; inst a decidedly longer period of time on account of the sat-infactory absence of sudden

## The Continuous Rail in the United States

## A Machine That Crimps a Head Section on a Rail

E Vielt since the fiange was put upon the car wheel instelled of upon the rail, engineers have sought to saudi the useless sorapting of the whole rail, when only 5 per cant to 6 per cent of its upper surface has been were away.

When ratio began to be laid in city streets, about of this small proportion of the rail would necessitate, not only the renewal of the whole rail, but entire recentraction of the track. Investors and engineers devised compound rails with the object of avoiding these costly renewals and hundreds of such rails were patented. The difficulty, which was never until quite recently overcome, was in statching the head or wearing surface of the rail to the base, or supporting members, so that the two members would hold fast together and withstand the vibration caused by the passing wheels.

Progress in rail-making and other atts, has made possible the system recently introduced into this country by a manufacturing company, after it had been tried out in Ragiand and France, where it is known as the "Rompase" rail. During the years 2011 and 1912, four miles of this system of construction were successfully laid in the circ of Chicago.

The rails were made of high carbon open-hearth steel. The head sections were applied to the base sections as to stagger the joints, and after being piaced in position in the street, the flangew of the head section were crimped under the false head of the base section in such a manner as to convert these flanges into springs having a grip of thirty-six tons to the running foot, which grip would easily withstand the streams developed by the heaviest electric locomotive. Only open-hearth steel could be used for the head section, as Hessemer is not sufficiently homogeneous and the larger percentage of theophorous present in high-action Hessemer steel makes it "cold short" and would cause the flanges to fracture doring the crimpina.

The latest development in electric motors had to be utilized to develop the power necessary to perform this

operation with satisfactory speed, and the highest quality of chrome-vanadium steel had to be used in constructing parts of the machinery.

In the process of manufacture the head section of the continuous rail passes through the mill in such a manner that it is more homogeneous, more close-grained, and of greater olectrical conductivity, than rails rolled in the ordinary say. It therefore exactly compiles with the conditions favored by the Committee on Standard Rail Sections, A S. C. E. 1889, who reported that "the grain, or fineness, of hot-rolled steel is governed by the work applied to it as its heat decreases," and "we are convinced that the wearing qualities of rails depend on the closeness of the grain of fine closeness of the grain of the closeness of the grain of the steel in their heads."

Tests made by the railway officials in Chicago show that the fine grained continuous rail head has over 70 per cent greater electrical conductivity than ordinary rail metal.

The staggered Joints and the spring artin of the bead faunces, make it practicable to use the rails as a hegative return, and each Chicago rail was found, after being laid to the track without any weided or other joint, to be equivalent to 2,289,000 C. M. copper. The value of this copper, laid in the street, any be taken at 90 cents per running foot per sulltion C. M., so-that its siddline to september 100 cents.

detailed in

ing the entire expense of bonding, there is a saving in copper cables which might amount in extreme cases to \$16,926 per mile of single track (2 ralls).

16,926 per mile of single track (2 ralls).

The area of electrical contact where the head of the

Mechanism for taking off wern rail faces from a

continuous rail is crimped to the base is (between the joint of the base and the joint of the head), over thirty times the area of the cross section of the whole rail, so that any loss of current at the joints is practically mediatibe. The saving in maintenance due to the elim-

ination of damaged joints would vary with every system, but may be taken roughly as (8) per cent of the total cost of track maintenance

When the continuous rall is worn out and has to be renewed, the saving in reconstruction in paved city streets ranges from \$10,000 to \$15,000 per mile of single track. In Chleago the amount of saving is estimated to be \$11,500 in another western city the saving is estimated at \$15,350, as per details given below

Saving	ln	rulis	<b>\$3,536</b>

\$15,330

The track hild in Engined in 1986 is still in operation and the plants show no legal of emplois, although the three behas been subjected to very heavy traille, so that were and tert on the radius stock from this cause is eliminated. In hying this track, care was taken that no head raths with upward kibss at the plants were placed in the track, and it is essential wherever the grand trac before the care are sum over that track and it is to be altered to the property of the care are sum over the track, and it is to be distributed to the corrustation in adjection of the corrustation in adjection track.

Similar raths were laid on a curve in the Parls under ground railway in a manner to thoroughly test the grip of the head rail flanges, where they stood the test with

Although the success of this system of construction has up to the present time been demonstrated only on street railway, it is advocated for use in main line railway construction as offering a solution to the problems connected with defective rule, which annually consessome two hundred

and forty accidents on steam railways in this country

It is evident that a defect or fracture in either the base or the head section of a continuous rail would simply result in another joint in the broken section, which would remain firm's held together by the sound section to which it is etimped

#### Rolled High-manganese Continuous Rails.

In adapting the continuous rail for underground initivals, it is advantages of staggering the joints of the head relative to the base sections, of the true alignment of meeting rails, of smooth ranalug, and of the absence of hammering joints and fractured rails, are all tended

The table are supplied in the usual bengths and composed of an open-hearth steel lakes rall, on to the top of which is etimped a rolled high-mannanes steel lakes are rolled in the mannanes steel lakes are usually as the result of the top of which is etimped a rolled high-mannanes steel lakes of rolled high-mannanes steel lakes are steel lakes as the steel of the base rall which prejects from these beyond the head roll at the other read, forming when the raths are laid in the truck stage read, or overlapping lobits

The rails are fished together with an improved combined spilee and sole plate placed center with the joint in the rails. Acting in conjunction with the (Continual on page 402)

Diver with salvage outfit appearing at the surface.

# Rescue Apparatus for the Crew of a Wrecked Submarine

By Dr. Alfred Gradenwitz

大きなななない いまいしいのないはんだいだいがん

Diving tests performed with the salvage outfit.

HERE are mainly three possibilities fiable to resuit in the wrecking of submarines, viz.: 1. Springa leak as a consequence of collision with another set or with the ground; 2, running aground by fulse maneuvers or fallure of the engine; and 3, fire or ex-

Most-of the fourteen submarine entastroubles on reord, all of which—with the exception of that of the German submarine "13"—have resuited in heavy losses of human lives, are to be ascribed to causes 1 and 2, and only those due to cause 2 in the end may be reduced to a minimum Existing safeguards against the caus coming under 3 are at present so highly developed that catastrophies ascriliable to them will always be of ex-ceptional occurrence. On the other hand, the serious dauger resulting from the first two causes is evident. and it is proposed in the following to disc available for facing it. The salvage aped in the following to discuss the means

paratus at present supplied by the oxygen industry may be divided into two groups, ulz.: 1, apparatus and devices for purify ing the nir (supply of oxygen and absorpthat of carbonic acid and extraled cases) : erging apparatus allowing the crew to leave a wrecked submarine

The apparatus for the parifying of air are mainly characteristic of German submarines. The nit exhaled by the men is regenerated from a store of compressed oxygen kent on board, its curboute acid being absorbed by potast cartridges regeneration continues without interruption until the available store of potash cartridges is exhausted. At moments of extreme distress and in the event of sudden fallure of the lighting plant, the crew will find at certain known places emerg-ency cartridges for immediate oxygen res-

The Installations for use in parifying air on submarines have already proved of inestimable value in an emergency would otherwise inve meant loss of life. The twenty-seven men rescued from the German submarine "13," which on January 10th, 1011, foundered to Kiel burlor. are sudebted for their lives to the regeneration of air with the notash cartridges. Ap-

paratus belonging to group 2 (emerging apparatus) form part of the salvage material of the German and some foreign submarine fleets. England has adopted pot-shaped diving belinets filled with alr which are thrown by the men over their head, shoulders, and breast, thus taking those equipped with the apparatus up The German submarines are equipped with a so-cuiled "diver salvage" outfit, comprising an emerg-ing and a breathing apparatus. Comprehensive tests baving shown its suitability, several foreign navies have adopted the same system

The "diver solvage" outfit has to perform three main tasks It is intended under variable water pressures to warrant a satisfactory respiration. It is to endow the man with sufficient buoyancy for reaching, m were automatically, the surface of the water, while allowing him to control his bnoyancy, so that he may joince even considerable depths (up to 200 feet) with-out any serious trouble. The apparatus is also designed to keep the man for a considerable time floating at the water surface

The whole outfit, when out of use, forms a little par cel cass to stow away. Its weight is about 6 klioames, to which a counterpoise 5.5 kilogrammes in weight is saided. The apparatus is out on like a waistcont and is ready for operation in a few seconds, with-out interfering with the movements of the body and head in the air or water. The ears remain ancovered, and the eyes can be protected by a pair of diver's goggles. The apparatus imports to the man and his outfit sufficient buoyanty even lu the event of its air being inactive. The man employed with the outfit can breathe one hour or breathe and work half an hour in vitiated

air (in the submarine), below and in water, as well as on land if he is again to dive below water or into viti-ated air The buoyancy of the apparatus at the surface lasts many hours without limiting lu any way the sensi

On account of these valuable features, the apparatus would seem to be suitable not only for rescue work in submarines, but at the same time as a useful adjunct for engineers called upon to work under water or in cavities filled with deleterious gases.

The "diver salvage" apparatus is based on the action of potash carridges used so successfully for mining salvage work. The outfit comprises a self-contained oxygen breathing contrivance with automatic air regen-eration and a swimming vest on which the various parts of the apparatus are fixed in such a way as to take up immediately their proper position when the

Salvage outfit for submari from the front.

Diver's salvage outfit

vest has been put on The breathing apparatus comprises the oxygen cylinder, the cartridge for ab sorbing the carbonic acid, the breathing bag carried on the back, the mouthpiece for mouth respiration, the nose clamp and some flexible connection tubes. The mouthpiece comprises two breathing valves insuring a continual circulation of air from the breathing bear through the potash cartridge, so that the air may return into the breathing bag in a purified condition. The exhated carisonic acid is absorbed completely in the potash cartridge. The oxygen required for respiration ls derived from the oxygen cylinder, and a store of compressed air serves to compensate any difference in pressure on emerging from considerable depths, any air submitted to surplus pressure escaping through ingeniously constructed valves.

a account of partial water investon and the impoerge to the surface, is lying at th at a depth of say 100 feet. The transversal bulkheads having allowed the endangered compartment to be left, the crew have gathered in the central compart where the air regenerator of the submarine will for e exclude any danger of suffocation. days to cor Should, however, the periodical air analyses have shown the vivifying effects of the regenerator to be doomed to exhaustion before the rescue work comment the surface may have advanced to the founders the critical moment has come to leave the submarine. It may be said that the crew immediately after the oc-currence of the accident had been ordered to equip themselves with the rescue outfit, with the handling which they are familiar through previous train

After fixing the order in which the men have to to the surface, all preparations are made for leaving to the surrace, an preparations are made for seaving the wreck. Since the latter is submitted to an outside pressure of 8 atmospheres (45 pounds per square inch), escaping is only possible after compensating the pres-sure in the interior of the submarine, which can only be done by allowing it to be flooded with water.

be done by allowing it to be needed with water.

After taking a deep breath, the men put the mouthpiece into their mouths, locking the mouthpiece tap
and putting on the nose clamp. The valve of the oxygen cylinder is kept open until the breathing bag is placed in position on the back. Everything is now ready starting on the last voyage which affords some chi at least of salvage. The moment no doubt is critical.

After loosening the bottom valves of the wreck, the water with a gurgling noise rushes into the compartment, surrounding the feet of those waiting to be

rescued, creeping up along their bodies and closing above their heads. However, in spite of the seriousness of the situation the men are for some time at least pro-tected by life-giving oxygen. The pressure on the cars after some energetic draughts is relieved. While the right hand is ap-plied to the valve of the oxygen cylinder, disengaging at intervals the supply of vital air, the left hand encompasses compressed air cylinder, thus compensating any pressure difference in the apparatus. After some minutes the whole compartment, spart from a layer of compressed gases, is filled with water. All lutches having been opened, a welrd green light penetrates into those depths, if the sun be shining above the waves. One after the other, the men now emerge from the hatches, seize the cable of the emerging buoy and the anchor ropes, and rise swift-ly toward the surface. The sir expanded in the apparatus escapes with a bubbling noise through an extremely sensitive com-pensation valve. The surplus pressure, which otherwise would weigh he the cheeks, throw the monthplece out of the mouth and crush the man, is never feit in a really disturbing manner After reaching a depth of say 50 feet, the man

stops for about 2 minutes and tries to animate his blood circulation by agilating his legs, snimate ms brood circumston by aguating ms legs, while allowing any stagnating nitrogen to escape. After a further pause of 5 minutes at a depth of 20 feet, the finel ascent to the light and to the courades engaged in the salvage work is accomplished. A safely working arrangement enables the man to throw breathing apparatus on reaching the surface; the up-per part of his body, however, is protected by the swimming vest, until he leaves the water.

## How Mold Fungi Live

C ABRYING out his researches on the nutrition of mold fungi, A. Kossowicz showed that certain fungi of lower orders, especially the aspergillus, penicitium, mucor and others, are able to assimilate ures and uri acid and to produce ammonia in consequence. Lately he finds that different species act in the same way in regard to glycocol and hippuric acid, and on the other hand he notes that some of these fungi are also able to utilize the utrites alone as a source of ultrogen. He even finds some specimens which develop very well in a glucose medium containing one per cent nitrite of potannus giving rise to ammonia. Together with Von from the group race to ammonia. Logenser with you Groller, he studies cultures of numerous spores and the-teria in mediums containing sulpho-cranic compounds, and it appears that some of these organisms are able to the such compounds as a source of sulphor and nitro-ges, but do not find in them all the carbon or nitrogen.

It is claimed that some of the escalppius of Australia are tailer than the California redwoods, which are commonly considered the highest trees to the world.

er that Lights the Ho An american mant Ligarat the frome PARTS inventor has combined a A ligarde with a small dynamo and stor-case bettary so that the sowery which the human meter produces when working the careriser, instead of going to warte, is stored up in the accumulator. The idea is a simple one, as will be observed, and in case the premises are not wired up for care the premises are not when the current the device may prove a most useful one for many purposes. In this way it is possible to use one or several small lamps for domestic lighting, so that the work done with the exerciser during the se can be taken advantage of in the evening. One point to be noticed is that the fact of using electric lamps gives a stimulus to the use of the machine for the e of exercise and is apt to prevent the daily exercise from being neglected, now that it becomes necessary. The present machine is designed to work several lamps with an hour's pedaling, and when there are several members of the family to use it, the number of lamps and the amount of light to be had from the device of course increases accordingly. Two sizes or course increases accordingly. Two sizes of machine are used, one to work with a storage battery of 12 volts and 12 amperes, this being intended for the use of not overly strong persons, while the second size is intended for use with a 12-volt and 25-ampere battery and serves for persons

# The Chagres River in Flood

A 8 we have explained from time to time in these columns the Chagres River, which so long proved a menace to the Panama Canal, has been tamed and put to useful work by the building of the Gatun dam and power plant. Some idea of the tremendous power of this stream when in flood may be gained from the companying photograph, which shows the waters pouring over the spillway before it was complet fulshed, the mad capers of this wild tor-fent have been overcome. The river, which was known to rise 25 feet in as many hours, is now checked by the hill of clay that closes the Gatun Valley, forming a te so large that the mighty floods the past now represent a rise measurable in fractions of an inch. The waters may be let off as desired and a large part of them is used to generate electricity for light and power throughout the Canal

# A Motor-driven Road Builder

A SELF-PROPELLED road building machine has been tested in Los Angeles with results that are said to be highly satisfactory from the standpoints of efficiency and economy. The engine which does all the work is a six-cylinder, distillate burning gas engine of 80 horse-power, which operates a series of bucket chains that dig the soil to any depth down to eighteen inches, and the tooth-armed an inches, and buckets are so powerful that they will cut through a finished pavement if it be de-sired to rebuild old streets. The earth is picked up by these buckets, carried to a mixer in the body of the machine and thoroughly combined with any desired binder, hot asphaltum or crude oil, and is then spread evenly and rolled, all in one operation. A trailer containing the binder follows the machine, and it is necessary to have a string of them in readiness as the device operates with great speed. The earth is dug up, mixed, relaid and rolled at the rate of fifty square feet a minute for an eight-inch depth of asphalt pave-ment. A very advantageous feature of this method of mixing is that it is uniform from base to surface, so that th is no danger of the surface's buckling. Of course where the mixture includes crushed rock, it is necessary to spread this material before the machine. The chains of buckets are independent of each other, or occeen are independent or each other and as each has a width of six inches it is possible to form various combinations for roads of different widths. The mani-mum number is aloved. Thus, for a twenty-foot roadway, the proper on

oline-electric plant for lighting a circus

ould be ten chains of six-inch buckets, so that four operations over the road would combine to make the required twenof width. The muchine was de signed by John Marray, a local luventor and road builder, and cost about \$30,000 It is a huge muchine with a length of enty-five feet, but a smaller and less expensive model is projected.

# Poison Bottle Alarm

W E can give no estimale of the namber of lives that have been lost or endangered by the careless one who picks up a bottle from his medicine chest in the dark. But this thing is being constantly done, and measures should be taken to prevent it. Recently the matter has been given prominence in the deliv papers, ow-ing to the death from this couse of several persons of prominence—It has been suggested that polsonous tablets be given a peculiar shape, different from ordinary tablets. Another suggestion is that the bottle be provided with a stopper from which a number of needle points proje so that the stopper can not be removed in the dark without pricking the fingers Still another suggestion (which is filus trated herewith) is to provide the bottle with bells that will sound a warning when it is picked up. If some or all of these methods were adopted, no doubt they would prevent many deaths and much suf

# Agricultural Progress in Canada

THE Canadian government has uppro-priated a sum of \$10,000,000 to cover a period of 10 years beginning with March 31st, 1913, for instruction and research in agriculture Purt of this will be applied to furthering the work of the Federal Department of Agriculture by assisting and developing the live stock, dairying, fruitgrowing and other industries along lines of investigation, improvements in trans-portation, etc; while agricultural education of all grades will be materially en The agricultural colleges are to be improved, elementary schools and short courses in agriculture, hortleniture and dalrying are to be established, and agriultural teaching is to be introdu the public schools. The sum of \$20,000 a year is allotted to veteriour, colleges.

# Modern Circus Lighting

ASOLINE torchilghts for the chr G have gone To-day we have in their place in the modern circus portuble electric lighting plant. The senson just closed saw two of the largest circuses equipped with the up-to-date lighting systems

The accompanying photograph shows one of the unit outfits of the 25-kilowatt portable gasoline-electric plants that have been manufactured by a well known company of electrical engineers especially for these circuses. The sets are made in units and a complete outfit consists of three trneks-two trneks currying cuch a dupilcute system, while the third truck is the care system, while the third truck is the snipply wagon and has monited upon its roof a powerful searchlight. This sourch-light is used especially for the aid of workmen employed in learning down tents, etc, preparatory to loudlog the circus There are also to the plant two 25-ampere spotlights used upon the stage

The outfits are mounted on one of the ordinary circus trucks whose ends and sides are removable. Each plant consists of a compound would, direct current generntor, built integral with the frame and direct connected to the shaft of a four eylinder, vertical gasoline engine. The set Is installed on the rear of the wagon with the flywheel at the onter end. At the front of the truck is installed the cooling system for the engine. This is a pressed steel radiator cooled by motor-driven fans

A 65-gallon cylindrically shaped water tank is mounted over the radiator. Un-derneath the truck in the center is swing the gasoline tank and engine muffler.

All tents are equipped with protected wiring which can very readily be either down or installed for use when necessary.

# Inventions New and Interesting

Simple Patent Law . Patent Office News . Notes on Trademarks

Recent Improvements in Conveying Devices THE imp riance of the problem of transportation is usef oridout. That the ramarkable development of the past bandred years w and never have been possible had not the railway and the steamship been invented is

a platitude

From the stand; it t of ec nomy money and e From the stated it to ee noney money and security strength in the cramp ring; thing does not change it. It follows that at a step which lessens the cost of transporta tler 13 d a li the art is a clear gain

the n v l st ps in the solution of the problem of trust rtatl ir liems usually bec me a matter of record by being jut nted. It is the jurpose of this article to call atten the briefly to some of the apparently more important h ventl us which have been patented during the pasyear in that branch f the art of transportation com monly known as c nveying devices or conveyers

Conveying devices as distinguished from cranes ele

vators, helsting machinery rallway systems and the like are chiefly of five types namely endless carriers recliptively of the types limited states and conveyers, fluid pressure devices and chites spouts or rollerways down which material is impelled by the in

Ordinarily conveyers move material comparatively short distances seldom more than a few hundred feet They are often found in relation to some machine or structure in which case they may become highly spe claimed in form yet retain and exercise but the one function-the moving of material-as in pneumatic stokers and furnace-charging devices

Endless Carriers Endless carriers are for the most part wheels the

axes of which may be either horizontal vertical or in clined, and helts Phe term belts is here used in a broad sense and includes endless chains of buckets and endless carrying cables as well as the ordinary

The flat belt has many desirable features. It is simple strong and has great carrying capacity. The last may be increased by the use of a series of trough ing rollers that tilt the edges of the belt up thus making its cross section trough shaped

A patent (No 1021846) on an improved form of troughing riller was granted to Mr R T Pearce of Montelair N J April 2nd 1912. To the roller shaft are keyed the usual central pulleys (Fig 1) This shaft is supported by and turns in two end pulleys of bell shape that are mounted in fixed journal boxes the belt passes over the set of pulleys the central pul the central pulleys, being of larger diameter than the central pulleys, being of larger diameter than the central pulleys turn in the journal boxes at a lower speed. The central pulley shaft turns in the bell pul kys at a speed equal to the difference in the angular speeds of the belf and central pulleys. The advantages claimed for this arrangement are that it is simple, and that the friction between the belt and the pulleys and between the pulleys and the journal hoxes is reduced

In case the flat belt is to be used on inclines some means must be employed to prevent the material espe-cially if it be of a granular nature from sliding or rolling back down the belt and accumulating at the bottom Slats hooks buttons and the like have been

Mr E C I Van Wert of Valhalla N Y has obtained a patent—No 909 419 August 1st 1911—on a device for this purpose consisting of a set of three plates that when attached to the belt forms a combined belt and bucket conveyer. The larger of the plates as indicated by Fig. 2 is riveted crosswise of the belt at its center Flanking the large plate at each side is a er plate similarly secured to the belt. of the small plates are connected to each other by a tension spring that causes the edges of the belt to tilt np or trough Thus this construction besides pre venting material from wilding down the belt also diss with the troughing rollers commonly used

In the past few years there has been considerable lemand for a satisfactory device for elevating ashes and other refuse from the basement of city buildings sidewalk Such a device should of course, be It should be collar sible in order that it may be stored underneath the sidewalk. It should be easily fed of large capacity so that it may interfere with sidewalk traffic as little as possible and should deliver material directly to a wagon or other vehicle stand-ing at the curb Reciprocating elevators blocks and tackles awinging cranes, and in a few instances end less carriers have been used for this purpose In a ent No 1025168 issued May 7th 1912 to August adh of Yonkers, N Y there is described a novel device of the last class

In this device as shown in Fig 8 a counter frame normally beneath the sidewalk carries a sidewalk over and als) supports a swinging frame Passing over a pair of sprocket wheels at the head of this swing

ing frame and around a pair of driver spreads located in a pit in the basement floor is an entitle of buckets. In use a wagon is backed, sip to the the counterbalanced frame is raised, the shafes ing frame swung out and an electric motor! lower sprocket wheels are driven is threwit tion. Material shoveled into the pit is deli wagon without further he

overlapping joints, this holds the rati maintains them against both vertical and maintains them against both vector and transverse stresses, but is sufficiently flex-ible and at the same time has a spring grip contact of such strength as to withtand the vibration and jarring set up by eavy traffic, and so effectually prevents the joint becoming slack or working loose It automatically adjusts itself to the rails and is more quickly assembled than the

Section of continuous rail, showing base rail and crimped-on head.

out in exactly the same manner as when using ordinary rails, except that the joint ing ends of the rails engage one over the other for a length of four inches.

Renewals of the continuous rail can be earried out with less interruption to traffic than on the ordinary system, as the overlapping joints will carry the trains be fore the rails have been fished together and while they are being fished.

# Recent Improvements in Conveying Devices

(Concluded from page 400.)

the return stroke. The material is thus caused to travel in a succession of for ward and backward steps in each of which the forward step is the greater. In the second type the load is moved forward by a bar or similar element upon which it may rest or beneath which it may lie. The feature that distinguishes this type from others, however, is that the load is supothers, however, is that the load is sup-ported, during the return stroke, by some element other than the bar which has moved it forward. Thus, there is applied to the load only a succession of forward

The supporting element may be anoth bar or series of bars, counterparts of those that have given the first forward movement. Each bar may consist of a series of parallel bars, in which case those of one set are arranged alternately or in interfingered relation with those of the other. Heretofore not more than two sets of bars have been used in a single conveyer-unit

Pierre Lorlliard of Tuxedo Park, N. Y., d a patent on August 15th, 1911, No. 1,000,828, on a similar form of conveyer in which three sets of bars are em-ployed. As shown in Figs. 5 and 6 every third bar is a part of the same set. The mechanism by which the bars are move is shown in Fig 5. The bars of each set are connected by crossbeams 5 that are mounted on sills 6. Each sill is supported on rollers carried by two similar rock arms 9 pivoted to rigid supports at 11. The tops of the rock arms are connected by a link 12 This link is pivotally connected to an arm 13 that is mounted to swing on the rod. Near the middle of arm awing on the content of that bears on the outer face of a cam 18 secured to power-shaft 17. Arm 18, mounted to swing on rod 19, is connected to still 6 by a pin-and-slot 20. A roller 21, near the middle of the arm travels in cam slot 22 cut into the face of the cam 16. Each set of bars is oper-

The Continuous Rail in the United which throws the rock arms to a position nearly vertical, thus eleviting the bars, the same time roller 21 evines as 18, causing the routing roll of the routing rolls of there to move longitudinally with set or pers to move longrenamenty went the load. At the end of the stroke the bars sink and deliver the load to the ris-ing bars of another set. The first named at then returns to its initial position. In installations comprising only two sets

motion that is said to be largely overcome by the present device. It is also said that less power is required than was necessary with the older forms.

Screw Conveyers.

The screw conveyer is particularly well
adapted to handle granular material. Its
most desirable features are its simplicity,
there being few parts, all of which may be protected, to a considerable degree, fr wear, and its compact form.

w conveyers are of two types. consisting essentially of a screw or he mounted upon a shaft that is rotatable in a fixed casing, and the other, a rotary cas-ing to which the blade of a helix or screw ternally attached.

The first type is the one usually em ployed. In it the screw has been driven heretofore by means of power applied at the end of the shaft. In installations of the end of the shaft. considerable length difficulty has be considerable length dimently has been ac-perienced because of the twisting of the shaft. The metal in the screw being farther removed from the axis of the shaft than the metal of the shaft itself, to twist. As a result internal stre in some cases have caused the blade to separate from the shaft have been set up. By means of the device patented by fr. W. D. Mount of Saltville, Va., on Mr

July 16th, 1912-No. 1,032,850-it is de signed to overcome this difficulty by drivsigned to overcome this dimenty by driv-ing the conveyer from a plurality of points along its length. As indicated by Figs. 7 and 8 this device consists primarily of a hollow sprocket wheel that is fitted beween the ends of adjacent sections of the conveyer easing. In order to prevent spilling of material, spring-held bearing rings are arranged to fit snugly against the opposite faces of the sprocket wheel. Pairs of rollers, mounted on the sprocket wheel, that travel on the outer surfaces of the bearing rings serve to center it in re-spect to the conveyer shaft. To the conveyer shaft is secured a radial arm that pair of lugs in the bore of the spr theel. Power applied to the teeth of the sprocket wheel acting through the lugs and arm rotates the co veyer shaft. Ther is no interference with the flow of mate rial in the casing.

Fluid Pressure Convey

Fluid pressure conveyers are of two types: In one, fluid under pressure high-er than that of the atmosphere is introduced behind the material: in the other tion. Both types are used to a large ex-tent in handling substances of granular or fibrous nature, particularly ashes, sawdust, cotton, grain and the like.
In patent No. 1,020,962, March 26th.

1912, granted to Cornelius Cable of Elkthe type first referred to above. The novelty is said to reside in a special form of nozzle through which the conveying on nozze through which the conveying fluid, in this case steam, is admitted to the conveyer pipe. As shown in Fig. 9, the nozzle is provided with faring ends. The nozze is province with naring ends. The end opening into the conveyer pipe has a smooth bore; the other is rifled or grooved internally. Upon steam being admitted the material is given a whiring motion

the conveyer tube. Within the past few years fluid presence conveyers, known as "nonumatic stackers," have largely displaced other forms used in carrying ettaw, from a threshing machine to a bars or stack. The puseumatic stacker consists of a fin and its casing, a conveyer tube, and a hood or ared by a similar mechanism, the three distributor that is statehed to the super mechanisms being arranged, however, 120 edgrees spart.

The operation is as follows: The rost-tree the strain, at various distances the strain at the substitution of the sum causes are 12 to swing been made telescopie.

# TRAINING **LEADERS**

The Interlaken School makes a business of training boys to be leaders, and employs the most efficient and logical meens to

Beath el bedy and mind is pro-moted by life in the open and first-hand field and ahop experi-ence with real things. The boys participate in the cultivation of the 600 acre farm on which the school is located. Interlaken boys have built their own plant and operate it themselves. The school comit themselves. The school com-munity is governed, under super-vision of the faculty, by the boye themselves. Interlaken makes a specialty of the study of science and modern industrial conditions.

Interlaken gives thorough prepasity or Technical School. Boys from 8 to 18 years old are taken. Oraduates of interlaken can spend a year in affiliated echools in Europe. In 1915 Interlaken will open its own branch in South Germeny, at which atudents can spend a year before antering tha universities of this country.

The next session of Interlaken beopens June 15th; cross - country excursions on horse back and camping expeditions to the Mi-chigan woods will be provided chigan woods will during the Summer.

# CRUDE ASBESTOS

R. H. MARTIN

A deridedly novel form of stacker tube to that instented by Mr. F. L. Sattley of Enthumpolis, Ind., No. 907,996, July 11th, generalpoon, inc., No. 201,200. July 121, 1821. 16. comprises a non-telescopic tube-saction having the lower half of its upper end est away as shown in Fig. 10. To the upper edge of the lower half of the tube-section is hinged a filer that consists tube-section is hinged a filer that consure of a number of hingedly-connected semi-cylindrical sections. A guideway 30 is secured to the lower side of the tube. A bar 38 carrying rollers 56 and hood or deflector 52 may be moved in and out along this guide, by means of an endle cable 30 and crank 43. The hood fits closely to and slides along the inner surface of the upper end of the tube. It is probable that the tube is more rigid than those formerly used since it may be made in a single piece.

Operation: Assuming the filler to be in

the position shown in full lines, material passing up the tube strikes the hood and in deflected downward. In case it is desired to discharge the straw farther out, the crank is turned, thus projecting the the uppermost of the filler-sections which the uppermost of the inter-ections when is thereby swung up against the tube. In this manner the cut-away portion of the tube can be filled step-by-step while maintaining a constant relation between the deflective and the end of the filler.

# Gravity Conveyers-Accessories.

It is often necessary to install convey-ers so as to carry material from room to room or from story to story. The passage-ways through walls or ceilings obviously become excellent avenues for the spreading of fire. Although building regulations in many cities require that provision be made for confining the fire to a single room, very few devices for this purpos

Patent No. 1,022,525, issued April 9th, 1912, to B. H. Alvey and M. U. Bernheim of Louisville, Ky., covers a fire-hood designed for co-operation with a rollerway As shown in Fig. 11 it consists of a metal frame, open at one end, that covers the opening in the floor. The opening in the frame may be closed by a door that swings on a horizontal pivot arranged across the upper edge of the opening. The door may normally hang in a vertical plane or may be secured to the roof of the hood by a fusible link. When closed it abuts against a filler that extends from the floor

to the upper edge of the rollerway. The operation of the door is of case the fusible link is not used, packages case the tunion link is not used, packages coming down the rollerway strike the door, awing it up and pass on, after which it immediately swings shut. When the link is employed the door closes only when the temperature in the hood equals or exceeds

# Losses in the Ohio Valley Flood

THE United States Geological Survey has just issued Water Supply Paper 334, dealing with the Ohlo Valley flood of Murch-April, 1918. In view of the widely divergent estimates of losses that were current at the time of the flood, and the fact that these losses were undoubtedly ter than in any previous visitation of the kind in the same region, much inter-est attaches to the figures on this subject collected by the Survey by means of circular letters sent to the officials of two hundred and six cities and towns in the should district. The losses reported by the towns in question, added to the losses reported by railways and traction lines, total \$180,878,097. These figures represent noral \$180,073,097. These figures represent actual damage, and do not include indirect, or "economic," damages. More-over, they apparently take no account of losses sustained by the rural community, suiside of town limits. Certainly \$200,—200,000 to account of the control of 600,000 is a very conservative estimate of the total actual and immediate losses. Considering that this loss was due to a single-dood, in a region in some part of shigh dood, in a region in some part of shigh Books occur from some to five times shigh year, one gathers an idea of the ha-hames wan of meany that the nation is justined in spending on preventive mea-ting. By A. RUSSELL BOND Author of "Scientific American Boy," "Scientific American Boy at School," and "Handy Man's Workshop and Laboratory"

6x81/4-275 pages-101 illustrations, including 59 page plates-

A BOOK of engineering for boys, telling m a boy's own way what every boy wants to know. It recounts the experience of two young lads who spend a summer vacation seeing the engineering wonders of New York. The boy with red blood in his viers will be thisled by the numerous adventures, all based on fact, showing courage, presence of much loyalty to comrades and devotion to duty: at the same time he will learn how the big things of engineering are being done. A dozen engineeri, experts in their several lines, have read and revised the manuscript.

Electrically operated butter churn and butter worker.

# Central Station Power for Farmers

Relieving the Tedium of Farm Work by the Use of Electricity

By D. R. Palmquist

 ${f R}$  EALIZING that the farm offers a large outlet for electric power, many central stations throughout the country have extended their transmission lines into the From these lines they are supplying the farmers with electricity for light and power particularly true of the States throughout the corn belt. The general farming in vogue there requires a targe amount of mechanical power, for grinding feed,

shredding fodder, cutting ensilage, thresh ing, and pumping water. The farmers throughout this region, the majority of whom are conducting their farms on a scientific basis, take to this new form of power as a duck would to water.

The manufacturers have done a great deal in making it possible to use electric power on farms, as they are now offering all sorts of farm machines readily adapt-able for electric drive. There is scarcely a modern electric device for the farm that is not effecting a large saving in time and is not errecting a large saving in time and a consequent reduction in the smooth of hired help needed, for most of the ordi-nary appliances require but one operator. In order to make this article more pruc-

tical and instructive, I will include some data and information, s cost of using electric power on farms.

Cost of Farm Installations.
At Eureka, Illinois, there are about At Eureka, Illinois, there are assu-twenty miles of transmission lines, tra-

remains a good around unitered. At the present time, there are about sixty farmers on these times. Most of them live near the transmission lines. Some, however, are not so near. This necessitates the building of branch lines, which is done by the company, at the expense of the farmer.

The company's plan is to place transformers in the most convenient place for distribution to three or more most convenient place for distribution to three or more farmers, if possible, and to require them to bear the expense of buildings the secondary lines from the trans-formers to their buildings. The farmer also pays for the wiring of his house and barns.

Motors are used for all purposes, such as pumping water, grinding feed, sawing wood, elevating grain into cribs and grammines, on cream separation, church, wash-oribs and grammines, on cream separation, church, wash-

ing machines, sewing machines, fans, and most of them use electric from.

Many have large tungsten lamps on poles in door, the was lightly to be a factor

barn and feed yards, and without exception they ap-

norn and reed yards, and untout exception trey ap-preciate these lights very highly. The following data show what it is actually costing the average farmer in this community to equip his house and farms for electricity, and also the new he finds for it.

Farm No. 1—Cost of wiring house and barn, \$80; cost of meters, \$51.50; number of lights installed, 30,

Electrically operated fodder cutter.

number of motors justified 2: size of motors 5 horse power and 1/2 horse-power. Farm machines operated by above motors: Feed grinder, grain elevator, cream

Farm No. 2 .- Cost of wiring house and barn, \$112. cost of meters, \$51.80; number of lights lustailed, 40; number of motors justailed, 2; size of motors, 3 horseower and ¼ horse-power. Farm machines operated by notors: Grain elevator, feed grinder, cream separator,

court, pump, wash machine, grind stone.

Form No. 3.—Cost of wiring house and harms, \$86;
cost of meters, \$51.50; number of lights installed, 30,
number of motors installed, 2; size of motors, 3 horsepower and 1/2 horse-power. Machines operated by above motors: Feed grinder, grain elevator, pump, cream sep-arator, wood saw, wash machine.

The above are typical of the average farm installa-

tions at Eureka, Illinois. As these farmers become more accustomed to the uses of electricity and realize its advantage, they will apply the electric drive to their many other farm muchines

Last January fourteen farmers petitioned the power

company at Eureka to extend their lines or limit elec-tricity would be available for their use. At that time the power plant was taxed to the limit, which did not enable them to take on any more custom-

They are now enlarging their plant and intend to take on these farmer

Operating Cost of Farm Machines.

Bearing in what that electricity is available for both light and power, let us see what it is costing these farmers to use electricity. Based on an average of 19 cents per kilowatt hom-equivalent to 71/2 cents per horse power hom - the cost of lighting amounts to a lifth of a cent an hour for a sixteen candle-power tangsten lamp. For power purposes the rate aver-

nges about 5 cents per kliowatt hom They say that when a horse begins to eat Its head off, there are two ways out of the difficulty Either work the beast hard enough to earn its keep or look around for a means of power with a more reas able appetite A one horse power motor costs approximately \$65, with an operat-ting cost sverigling 5 cents an hour. A good horse costs from \$150 to \$250, with an operating cost averaging 8 cents an hour

A one eighth horse-power motor equivalent to one man power costs \$40, with an operating cost of less than one cent an loan. The Department of Agriculture states that the farm horse averages about 3½ hours of work a day the year round, and be eats folder steadily. The electric motor, on the other hand, consumes energy only when it is in operation

Now let us consider some of the farm unrelines to which electric motor drive has been successfully piled and from which the cost of operation has been deduced by authoritative tests. These tests were made under actual working conditions on farms, and though the figures are susceptible of slight variation, due to individual controlling circumstances, they afford a fair standard in considering the advisability of using elec-tric power on the farm. All operating costs are based

(Concluded on page 417.)

The Editor is always glad to receive for examination illustrated articles on subjects of limely interest. If the photographs are shorp, the articles short, and the facts sublicitic, the contributions will receive special attention. Accepted articles will be paid for at

The purpose of this fournal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

# Rest and Railway Safety

EVERAL years ago, when the New York Central Railroad inaugurated the twenty-hour service to Chicago, the Editor of this formal. Chicago, the Editor of this journal was given an opportunity to ride in the cab of the several engines which pulled the train over the various divisions. On the round trip he rode on some eight or nine engines and talked with as many different enginemen. Subsquently, he met by appointment the engineman wi emen Subse covered the run from New York to Albany and back, a veterau in the service. He was tall, well set up, clear eved, of ruddy complexion, and in his off-duty clothes he might readily have been taken for a prosperous, well-preserved business man of sixty years. We mention preserved business man of sixty years. We mention these facts because at the outset of our talk about his experiences, he told us that for thirty years he had been at the throttle of the fastest expresses that were run out of New York city on the New York Central system. There is a popular impression that the man who pulls an express train is subjected to such severe mental strain, that, after a very few years, he has to be transferred to less strenuous work on slower local trains, to give him an opportunity to recuperate; yet here was a man who had been doing this work for the greater part of his working lifetime and had come through it in perfect physical condition

we spoke of this popular belief and asked what was the secret of his successfully carrying such heavy responsibility without any impairment of his physical or mental equipment. "It may be," he said, "that I um temperamentally suited to this work; but my own selled is that my present physical condition is due to the fact that I have taken the very best care of my health by abstaining from stimmiants, keeping regular hours, and above all, being careful to get sufficient sleep

Now this little talk of many years ago is brought forethly to our recollection by a document, sent out by the Pennsylvania Ballroad Company, which states that it is considering the advisability of establishing a rule, that employees must live or take their rest sufficiently near to their work to enable them to report for duty any hour, day or night, with not more than one hour of necessary traveltug between their homes or restlug places and the point where they begin work. The state ment goes on to say that many cases have come to the notice of the management, wherein men are living considerable distances from their place of work, and that though they spend only a reasonable time on duty, so much additional time is required in traveling to and from work that they do not have sufficient rest and recreation. In some instances men live from 50 to 100 miles from the place where they report for daty.

If this company should take well-considered action in the matter, it will establish a precedent which should be followed by every railroad throughout the country and we believe that the present is a very opportune time to set such a movement afoot. The terrible disaster at North Haven on the New Haven Railroad is fresh in the public mind. In their investigation of the accident, the Interstate Commerce Commission found that in each twenty-four hour period, Engineman of the colliding train, mainly because he lived a considerable distance from the point where his run begon, had best than six hours of rest in bed us-his home. The Commission stated in its report that no engineman who took his rest in such a manner as Engineman Miller did while performing double duty, could be in proper physical or mental condition to perform the exacting service required of an engineman on a high-speed passenger tran.

We are in hearty accord with this opinion. It would

we are in nearry accord with this opinion. At would be possible to establish a rule which would equitably cover every interest involved, so that the men may have every reasonable freedom in directing their private lives to suit themselves, but always under the wate nives to suit themserves, but always more the eliphalton that they shall live or take their rest at points which will enable them to report for work with-out undue time being consumed in their doing so. Con-dideration of the interest of the traveling public, the railroad companies, and of the trainmen themselves demands that specific rules should be laid down cover ing this most important question.

# Not Sea Water, but Sewage

MONG the long-neglected municipal problems which will confront the lately elected adminitration of this city is that of sewage disposal than which, surely, no more vital question affecting the physical well-being of the five million inhabitants of

New York can be found to-day.

There is a popular and altogether erroneous belief that because there are tidal movements in New York Harbor, and because there are heavy currents in t North and the East Rivers, the sewage of the city is no sooner disgorged into these waters, than it is swept away, carried out to the Atlantic, and harmlessly dissipated in the sea

As a matter of fact, nothing of the kind hap The huge floods of sewage (they are nothing less) are discharged into the rivers and the bay and there their solid contents are deposited and there they remain twenty-four hours there is poured into the Hartem River ninty-nine million gallons, into the North River one hundred and thirty-two million gallons, and into the East River two hundred and sixty-four million gallons of sewage. And this, be it remembered, has been going on in its relative proportions for centuries. The flithy deposit resulting from this back-yard method of disposal has steadily accumulated, until the waters that surround this, the second greatest city of the world, are underlaid by an unmentionable deposit, the mere thought of which should bring a blush to the check of every citizen in this age of advanced ideas as to cleanliness and decent sanitary habits

That there is movement in the waters of the bay and river is true; but it is a movement merely back and forth. There is no endless sweep of the whole mass of water out to the sea, and the substitution of unpolluted water in its place. The Metropolitan Sew-erage Commission of New York proved this to a demo-stration by placing flouts in various localities and recording their movements. One of these floats put in the East River, traveled in 78½ hours a distance of 107% miles, at the end of which time it was picked up one mile from the starting point. After lear this, need it cause any surprise to learn further, that every year the Department of Docks and Ferries dredges out some 400,000 cubic yards of deposit from the slips and docks of the lower East River, to say nothing of large quantities that are also dredged out by private enterprise?

Now the Sewerage Commission, which is of engineers of international reputation, has drawn up a plan of sewage disposal, which, if followed, will serve to clean up the maritime backyards and alleys of this city, and substitute in New York conditions that are wholesome and decent In this plan the Harlem River is taken cure of by trunk sewers which will lend to a large settling basin at Ward's Island, where the solids will be taken out and either burned or carried to see in barges, and there dumped. The North Shore of Long Island, within the city limits, is to be provided with a similar trunk system, with a settling basin for a like method of treatment at Tallman's Island, on the Sound. The greater part of Manhattan is to be served under the proposed scheme by smaller local set-tling basins, located at the foot of various cross streets, e the solids will be incinerated. are to take care of the sewage of the East River from Newtown Creek to the upper end of Blackwell's Island The worst and most polluted section of the East River from Newtown Creek to the Battery will be relieved by the construction of large, main sewers along the opposite shores, the contents of which will be led in a tunnel reaching below Brooklyn to Coney Island, and thence to a largo settling basin, built three miles out at sea. From this the siudge will be taken in tank steamers and dumped 90 to 100 miles out at sea.

The plan of disposal, as thus worked out, is based upon methods, the efficiency of which has been amply demonstrated in existing plants erecywhere. It pre-sents a ready and not too costly means of escape from the present, intolerable conditions; and it is to be hoped that the incoming administration will make this one of the earliest measures for civic improvement to receive their indorsement

Engineering Competitions in Gar Navy
HE European eraise of certain satisfaction of
Atlantic Flort will furnish an excellent oppotunity for close competition in suginecting service conditions; and the performance of the service conditions; and the performance of the washing orusing the Atlantic together in the vorgage to said from the Mediterranean will be washed with the clea-test attention. In the days of the satisfies also; the amount of freeh water available on board was to the which generally gave the greatest concern; but the cli-limportant factors for the seaman are now the damost of fuel on hand, the amount that must be expected in steaming so many miles per hour, and that ne for the maintenance of the officers and men. of the extent of our coast line, and of the distances which our vessels may be expected to cover in the event of hostilities, mobility for ships of all classes comog our fleets is the first requis Steaming Navy.

In Rio de Janeiro in January, 1908, the commander-in-chief of the United States Atlantic Fleet, which was then on its celebrated cruise around the world, is then on its ceiebrated cruse around the worm, seeing an order insugurating the competition in engineering for the bettleships and destroyers composing the feet at that time making the voyage to the Pacific. The competition included the development of maximum competition incinced the overlopment or maximum speed under forced and natural draft, and economy of coal and oil under these, and under ordinary cruising conditions. Breakdowns were penalized and water, when received from an outside source, was charged against the ship receiving it. This competition ended against the ann receiving it. This competition enter upon the arrival of the fleet at Magdaleua Bay, Lower California. The distance steamed was 8,210.5 knots, and it was estimated that a total not increase in economic to the content of the conten omy of 1,400 tons of coni was realised. directly due to rovements in methods.

Taking the performances on the voyage from Rio to Taking the performances on the voyage roun and to Magdalena Bay as a standard, it was estimated that 2,425 tons of coal was saved on the run from fan Francisco to Manila Bay. On the same basis it was also ascertained that over 8,000 gallons of lubricating oil was saved. Two vessels more than doubled their cruising radius as far as oil was concerned.

Despite the unfavorable weather encountered on the oyage across the Atlantic when homeward bound, and the long time which had elapsed since the last docking the long time which had elsawed since the last docking of ships, the saving it used compared with the trip from Hampton Roads to Rio on the outward voyage amounted to over 5.5 per cent. The results obtained on this cruise sufficiently demonstrated the advantages of competitive methods, and in June, 190.8, general order from the Navy Department established the engineering competitions as a permanent feature in the operation

Winning vessels of the different classes each year are awarded the trophies, consisting of bronse plaques, which are carried by them for the succeeding twelve months as symbols of their efficiency. Each petty and man of the engineering department of a ship win-ning the trophy is allowed to wear a red letter "E" on the sleeve of his uniform, and these emblems are greatly esteemed by the individuals who have striven hard for twelve months in an unremitting effort to produce economy and efficiency in their department. The commanding and certain engineering officers of a winning vessel receive commendatory letters from the Navy Department

But few of the visitors to warships have any idee f the details to be mastered, and the work accomor the details to be mastered, and the work accom-plished in meintaining the power plant intailed on a modern dreadcought. They have no conception of the devotion to duty which is necessary on the part of each individual working in his own, sometimes obscurs, uncomfortable, and frequently dangerous, corner, with the full knowledge that he must do his part to the end, out of the sight of men, and without the recognition which those who work in daylight above him may The toll of death due to casualties in engis and fire rooms far exceeds that in turrets and mage sines; yet there has been no shrinking, and no holding back. There is no class of men on board a ship with a higher sense of duty, better discipline or tradi or who are more apt to acquit themselves with credit in time of stress than the members of the engineer's division. Their duties are of equal, if not greater, inportance than those of their shipmates who fight the guns. It is as necessary for a ship when called upon guns. It is as necessary for a ship when called upon for battle to reach and to maintain a station favorable for the fighting as it is to show accuracy and skill in for the dighting as it is to show accuracy and shill in gumery after this station has been reached. The men-below cannot hope to see, or to know, what is taking place in the outer world in the final and supress test for which a battleship is constructed. Without the worste, and the training which will insure a proper per-formance on the part of what has been called the "binds gang," success on the day of battle will become imple-sible. To assist in this necessary training and indirac-tion the engineering competitions are doing they pre-form the contenting competitions are doing they pre-formation. The collection of yantable, girts they then ser-vice, most satisfactory require him to be the ser-vice, most satisfactory require him to be the service. 

# Electricity

Processing of Chemicals of New Merchiga.—On November 1et, 1913, the vessify under construction for the United States. Mary. 1000, completed to the following exists: "New York" at the Brooklyn Navy Yard, 99 per equi; "New", "96 per ent; "Novada," 40,2 per cent; "the "Olikhorsa," 18.7 per cent; the "Pounsylvania," 11.8 per cent; and No. 20, the sister ship to the "Pounsylvania," 11.8 shout to have he held like the New York Yard, is shout to have he held like.

The state of the s

A 38,000 tilevest Turbine.—The Interborough Rapid Transit Company of New York city has recently placed an order with the Westingbouse Machine Company for a horizontal turbine of 20,000 kilowatte capacity. The minister of this particular unit will be fix division into two furbine elements; the high-pressure element being a single-flow surbine, operating at 1,500 revolutions per minute, and the low-pressure element being a double-dow turbine, operating at 1,500 revolutions per minute. And the low-pressure element being a double-dow turbine, operating at 1,500 revolutions per minuse. The machine is of the reaction type throughout, and comparatively low blade speeds are involved.

Danger Signals at Grade Crossings.—The Lehigh Valley Raliroad is installing at highway grade crossings danger signals which should prove to be very effective. As soon as a train comes within a mile of the crossing, the signal shows a red light and a gong that can be heard five hundred yards away begins to ring. Both warnings continue to set until the train has passed, when the gong ceases and the red light changes to white. Should not wires become deenaged, or should anything happen to the mechanism, the signal on the disk fiashes to danger and remains there until repairs are made. Nothing short of sotual demolition can prevent the signal from working.

Consuracha Silds Is Cut Through.—The great Cucuracha silds on the Fanama Canal (which, it will be remembered, Bilds the Culders out in the interval between the cossation of excavation and the flooding of the out with water) has at least been cut through, the opening having reached, according to the last dispatches, a depth of 40 feet below the present level of water in Gatutt Lakes and in the out. A vessed carry, it certain officials of the read pessed through, and now that the contract of the read pessed through, and now that length of the contract of the length of the contract of the contract

New Steel Regissent for the New Havan—The first of the new steel cars ordered for the New Haven road has been received, and by the end of the year it is estimated that twenty-five of these will be placed in service. The car is 80 forct in length, and has a sesting capacity of 39 persons. The heating system is regulated automatically by pressure. Each car is furnished with its own lighting system, the ourrest being generated by a dynamo which is run by a belt at tached to the car ards. The floor consists of sheet steel with a composition covering that is freprotor, and the cars are also protected from the heat in summer and cold in winter by a heavy insulation of hair felt and asbeston.

A Seet and Dust Gage.—According to the Electrics, an organized attempt to measure, by means of instruments standardised by the Smoke Abatement Committee, the extent of the soot and dust existing in the stanophers of several large towns and oblies in the United Kingdom has been undertaken, commencing from the first of the present month. The instrument to be used follow the principle of the rain gage a given area being exposed to each all solid matter that either fails by gravity or is borne down by rain. This is collected in a giase receiver placed beneath a duct leading from the collecting surface. The receiver till be removed once a month and replaced by a fresh one.

Test of Asbekan Dam Shaft.—With the exception of some finishing work in the Carrison tunnel, the Catakill Aquaduct is now practically completed from High Falls to Hilleville Reservoir, which lies on the outshirst of New York city. On November 11th water from the Ashokan Dam was sent through one of the great shafts of the Aquedict, namely, shaft No. 1, which is situated at Stone Ridge. The water reaches a point seven hundred feet below the surface, at which level it is carried below the Rondout Valley for a distance of about its milles. The test was completely successful. Other shafts will be feeted in the same way, successively, until the whole switch has been tried out.

the whole system has been tried out.

Artasian Wells in Americals—"It is interesting to recollect, says the Engineer, that over a very large man of Australia, and especially where the rainful is light, it is possible to tap an apparently inenthaustille singly of artasian water, by bottog. In this way much has been added to the value of large tracts of country, both for scote carrying and general productive purposes. Lebent developments would seem to indicate the present developments would seem to indicate the present developments would seem to indicate the present of th

the Committee of the Committee of

Electric Wisdow-cleaning Dovice,—According to a press report, Admiral Prince Henry of Prussia, brother of the Kaiser, has invented and patented an electrical dovice for cleaning the windows of automobiles in rany or freety weather. The device is set in operation by the pressing of a button.

of a button.

Electric Bulletin Board.—A large electric news bulletin board has been erected in Dayton, Ohio, with which news is spelled out in luminous letter measuring 28 by 22 miches. The announcements may be read at a distance of four blocks. The board has a capacity of four lines of fitneen letters to the line, and is operated by a keyboard similar to that of the typewriter.

Electric Vehicle Census.—The Electric Vehicle Association of America estimates that there are 37,000 electric vehicles in use in the United States, of which number about 25,000 are pleasure cars and 12,000 commercial evhicles. Chicago holds the record with 2,800 vehicles. New York with 2,000 comes second, and Cleveland with 1,000 comes third. Forty per cent of New York's motor trucks are electrically driven.

Lightning Conductors on St. Paul's.—Now lightning conductors have just been installed on St. Paul's Catheria in London, and in the ocurse of this work the interesting discovery was made of a part of one of the original ron bar conductors erected about 140 years ago under the supervision of Benjamin Franklin. This bar, which was inside one of the towers and so not exposed to the weather, was still in a good state of preservation.

Motor Tracking as Night.—In his presidential address before the Electric Volicile Association of America, Arthur Williams suggested that traffic organization in New York and other bury oftise could be relieved by nihibituding high for day tracking. There is no reason why wholesale trucking could not be done at night. Goods may be moved from the terminant to warehouse and the moving in large quantities of merchandice to the large department score done not have set be done in the day title of the control of the c

1.200-Volt Line in Holland.—A short interurban traction line is now in operation in Holland connecting Leyden with the two towns of Kabwyk and Noorwyk. It runs on the continuous current 1.200-volt system to the standard gaze, using double track for the most part. After leaving the city limits, the road reaches the town of Ryashurg three miles sway and at this point it divides into two branches which run to the two places just anamed, these being sea beaches on the North Soa, lying at 5 and 7 miles respectively from town. Current comes directly from the Layden central status without the use of substations. Trolley wires are held by middle poles between tracks carrying double bracket arms Trains run every half-hour and are made up of a motor car and two traillers. Motor cars have two ond clabins for controllers and carry two 100 horse-power motors which take current at 1,200 volts by pantagraph trolley.

Carbons for Searchighta.—In most reserchlighte the rays come from the positive carbon of minoritant point is to have a stoady are. Thu is about satisfied by the use of a negative carbon of small diameter, but with large apparatus using heavy currents, the anali carbon soon becomes red for quite a length and burns up quicily. Should the small carbon he inclosed in a tube, this will cast an objectionable shadow. Gen man countractors reduce the was of the negative carbon by placing it in gas or vapor contaming no cargent and which takes off the heat. Again, lengthwise or cross grooves in the carbon, in a refractory material, the carbon consumes faster than the core and this produces a fine point. A good method is to use a current of coal gas escaping from a pipe, and this gas can even be lighted without harm. Solids or liquids, such as naphthaline or petroleum, can also be vaporized by the heat of the arc.

but he see to the arc.

A Reading Optophones.—A year ago an instrument was developed which enabled a bilind person to discover the whereabouts of windows, lights and light objects, by sound. This instrument, known as the optophone, made use of the varying resistances of eclenium cells when exposed to light, and made known the presence of light by means of a telephone. The apparatus has since been improved, to the extent that it is now possible for a blind person to read type. So far the smallest type that may be successfully read is an inch high and it must be photographed whife, as a transparency. The letters of the control of

# Science

The Humers of Science.—Among the list of new books published in a resent copy of Nature we find the following: "Ist es wahr data  $2k^2 = 4$  sit" (ist it rue that  $2k^2 = 4$ ) by Fred Bon First volume  $\delta \mathcal{L}S$  pages. Published by E. Renneke We leave it to the reader to make his own observations.

The Return of Peary's Record.—It is reported that the record deposited by Peary in a carra at Navy Cliff on the northeast coast of (treveland in July, 1882, has been returned by Knud Rasmussen, the Danish explorer who found theoreof. The Danish government, to whom the record was sent by Rasmussen, has officially transmitted it to Admiral Peary.

The Results of Anti-typhoid Inoculation among the French troops in Algeria and Morocco during 1912 were reported by Prof. Vincent at the revent International Medical Congress in London. In western Morocco, while about sateen per cent among the non-nouvaleted contracted the disease, only one in 5,000 among the inoculated dist.

Hans in behavior der Meteorologie. There is perhans no branch of serence in which a single text-book holds a more dominant place than does Hami's Lehrbook in meteorology. It is, therefore, interesting to learn from a note in Screece that a revised edition of this work is in an advanced stage of preparation and will shortly begin to appear in parts. The author expects to complete the work in the autumn of 1914.

Rubber From Wild Letture.—A study by C. P. Fox of two "species of wild letture, Letture considerate and L. Scarzida, both common in the northern United States, shows that the former contains 2.19 and the latter 1.58 per cent of a good quality of rubber. As the plants also centuan lacturerum, which is a recognized drug, it is suggrested that they might be profitably exploited for both these products.

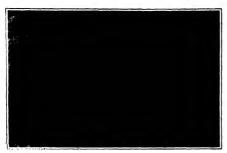

The Purification of Public Water Supplies.—This is the subject of an important momor by George A. Johnson, published as Water-Supply Paper 315 of the U. S. Geological Survey It includes descriptions and illustrations of all the principal filtration plants in the United States, together with a full account of the recently developed methods of water surination with hypochlorites, and the methods of water softening used at a number of municipal plants in the country.

The Chemical Intensity of Sunlight, together with its fluctuations, has been investigated by a great variety of methods, with hardly comparable results. One of of methods, with hardly comparable results. One of the latest undertakings of this kind was earned out at the Hawaiian Agricultural Experiment Station, in co-operation with the Philipane Bureau of Science. Using a solution of exalte acid in the presence of uranium accetact, it was found that the actime effect of the sim was implied at the spring and fall equinoxes, and lowest at the summer and winter solicities.

Aerated Waters in India. A consular report states that the enormous number of Brahmms and Mohammedans in India whose religions strictly prohibit the draiking of alcohole beverages are finding in aerated water a substitute that volaties no religions principle. Among natives of the strictest caste prejudices, who are ordinarily aerated into to our ordinarily shifting that has been prepared by persons of other castes, no objection seems to be raused to aerated waters, which being made by machinery are considered free from con-

An International Institute of Social Statistics.—An international institute is being formed to collect and compile figures on subjects which are barometers of financial, industrial, trade or secuel conditions. It is proposed that monthly figures of the subjects mentioned shall be called by the different nations on a given day sach month to the office of the institute for immediate which is not to be subjects and the subject in the subject in the subject is not only to the subject in the subject in the subject is not only to the subject in the subject in the subject is not only to the subject in the proposed international institute may fulfill successfully this very important function.

Sea Routes to Siberta.—From time to time the GERENTIFIC AMERICA's his recorded the attempts that are being made to establish regular wa routes to the Arcue coast of Siberta from the European solar and also by way of Berning Strait. On August 6th Dr. Nansen left, Varido, Norway, in the steamer "Korreet" for the mouth of the Yunisic River. A Russian government cargo is to be carried to the Yunise and a private necessarile cargo on the return voage. As we have previously reported, the Russian authorities recently established variety estations on the Yugor and Kara Straits to notify vessels whenever these outrances to Kara Soa are free from no. According to the reports thus received, the "Korreet" will pass through one of the straits mentioned, or through Matyushin Strait, or will crummavigate Nova Zemida. It is hoped that Dr. Nansen will obtain some tidings of the missing Brunsloff expedition, which undertook leat year to make the Northeast Passage by way of Parins Refrait.

Zoology Hall arranged for breeding small aquatic animals.

# A Laboratory for Investigations of Underground Life

A Grotto Utilized for the Study of Subterranean Plants and Animals

By Dr. Alfred Gradenwitz

THE organisms inhabiting the bottom of the sea have, until recent times, been omitted from the have, until recent times, been omitted from the scope of scientific investigation, and the fauna and flora of caverns, so remarkable on account of their peculiar conditions of existence (absence of light, uni-formity of temperature, cto.) have ilkewise been

408

sgiected by scientists until quite recently. A French naturalist, M. Henri Gadeau de Kerville, A French naturalist, M. Heuri Gadesau de Kervini in connection with his excessations while searching for remmants of perhistoric man, discovered a large cavern in an abandoned quarry near 8t. Peer. Being greatly interested in spelcology, he decided to prepar-tise cevern at his own expense as a laboratory for investigating underground life. This remarkable in-stitution, on account of its sessentific importance, has

created a great interest among scientists in general.

The laboratory is situated in calcareous rock The laboratory is situated in calcareous rock and comprises a staircase, a corridor, a ventilation chamber, a vestibule and the laboratory rooms proper. The last include a zeological and a botanical hall and a hall and a back room. Apart from the staircase, corridor and ventilation chamber, the whole laboratory covers an area of no less than 671 square meters.

of no less than 971 square meters.

To the left of the entrance there is a concrete water tank of 2,025 liters capacity. From this the water is conveyed through an underground conduit into two steedments tanks in the zoology hall where aquatic animals are kept. From the entrance door there is a concrete starces of forty steps leading down to the corridor mentioned above. On the left is the vertilize chamber which through windows states with two tion chamber which, through windows fitted with iron blinds, communicates with the corridor and vestib The ventilation of the laboratory is excellent. after many hours spent there, one never has the least feeling of being in confined air. Ventilation is effected through the entrance door, the ventilation chamber, a ventilation window in the zoology hall and a large rectangular chamber in the outer wall of the two laborarecongular commonly in the during wall of the wall also re-tory halls. This wall is bined with a thick layor of earth and stone to protect it against atmospheric in-fluences. A sunshade on the western window of the hall protects this against any reflected daylight hable to enter through the ventilation chimpey Since the laboratory lies in the open country the air in its interior is, of course, of the greatest parity, which is most important in connection with any research rk on underground organisms

In the vestibule there is also a tarred linen curtain In the vectionic there is also a tarred men curtain which, in bright daylight and especially in the event of the sun rays striking the entrance door, wards off any reflected light. As there is absolute darknoss in the two laboratory rooms, there is no need for the walls and endings being blackened. In front of the protective curtain is a table for preparing the plants to be used for experimental purposes; belilud this table is an insect car

The zoology hall contains four aquaria, the two sheetmetal water tanks above referred to, sixteen concrete troughs, a sink, a concrete slab, and on two long tables twenty-four wooden boxes. Some of the concrete troughs twenty-tour wooden hoxes. Some of the concrete troughs are fitted with liels, thus preventing the animals kept therein from escaping. The water from the four aquaris is discharged through a tap into buckets; a hand pump or syphon serves to renew the water in the iron concrete troughs. Since the air is saturated with mosture there is practically no vaporization of water, and on account of its low temperature the water decays with extreme slowness, thus necessitating a renewal

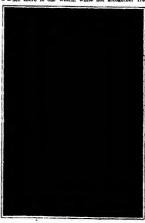

at very rare intervals. On the wall there are several small outlets to the discharge conduit, into which any superfluous water is poured. Candle lanterns with yellow and green glasses are used for lighting. These sufficient light to pass, though arresting practically all chemical rays.

The botany hall contains four border-beds containing The notant hast open and one of the continue o

temperature of the air (generally 5 to 9 deg. Cent) varies only a few degrees in the course of the year, in spite of the excellent ventilation. The water year, in spite of the excellent ventilation. The water temperature throughout the year is 7 to 8.5 deg. Cent. M. de Kerville does nothing to prevent an increase of temperature in his cavern laboratory. However, when the outside temperature is excessively low, as an additional precaution he puts a straw mat on the en-trance door, which, though interfering in no way with ventilation, constitutes an effectual protection against the cold. On account of the uniform temperature, the great moisture of the air and the perfect darkness any plants and animals studied in the laboratory are practically the same conditions as in real grottoes on promises to prove of the greatest utility to scientific investigation

# Animal Training by Magnetism

A MONG the various applications of the electro-mag

Botany Hall, where underground plants are

from the imputation of humbugging the public, has at least the merit of much ingenuity, and may suggether and more creditable services.

Oner and more creatures services.

A genial showman, not so very long ago, happening to see the case with which a powerful lifting magnet was used to handle material, conceived the idea of employing a similar device to assist the performances of a "trained" elephant. The plan was nothing less than the use of what might be called magnetic stencils, to enable the intelligent beast to appear to solve problems in arithmetic and write answers to simple questions
It was found entirely possible to train the elepi

to take up in his trunk an iron holder containing a piece alk, and to move it about over the surf blackboard. The problem lay in the conversion of these nimless scribblings into intelligent and correct rs to questions put, either by the trainer or by the endien

The sight of the lifting magnet gave the showman the ciue to his solution. Before long his exhibition included a wagon with a binckboard side, as thin as might be conveniently made, and containing within it a complete conveniently made, and containing within it a complete equipment of large letters and figures arranged as poles to a powerful magnet, which could be held up, against the inside of the blackboard by an attendant. The attraction of three magnetized symbols was sufficlent to guide the holder in the trunk of the elephant as it was simlessly moved over the surface of the blackboard, and thus the intelligent animal was enabled resa the admiring audience with his ability to write the sums of small numbers and do other things indicative of the possession of human reasoning powers

In view of the interest now expressed in intelligent horses and similar animal marvels, it may be of inte est to examine the extent to which the latest devel ments in applied science are being used in such fields as the entertainment of a circus audience. Possibly the explanations which this line of inquiry may suggest will be as entertaining as the show itself, and very probably further applications will occur both to showman

# Excessive Whaling in the Southern Ocean

Exceesive w maning in the Southern Cream

W 1711 the recent great development of whaling in

W 1711 the recent great development of whaling in

other natitudes has arisen the danger that some

other favorite whaling grounds will soon be worked

out. Thanks to modern methods and apparetus, whal
ing is much more deadly to-day than it was in the

uniny whaling days of the last'century; not only are

more whales of a given species destroyed in proportion

the number deposits of the statement of t to the number encountered by the whalers, but it is ofitable to hunt species that were form ht worth the attention of whalers. During the year 1911 about 17,500 whales were caught in the southern hemisphere, yielding 500,000 barrels of oil, valued at \$8,750,000; and the total catch in 1912 is sup have been 10 to 25 per cent greater than in 1911. South Georgia, where the whaling stations are leased by south recogni, where the whating stations are sensed by the British government to a Norwegian firm, 7,000 whales were captured in 1911, the species hunted in that vicinity being chiefly rorquals, which were once that vicinity being entery requisa, warps were used left in peace by whalese sing account of their relatively small yield of oil and whatebooks. The British Colonial Office has just sent Major Barriet Significing to this whating ground to accertain whether the whales stand in danger of extermination. He is accompanied by a surfamember of the British Managem, who self better rmist of the British Museum, who will bring

# What Is Old Age?

# Carrel's Research on the Mechanism of Physical Growth

By Genevieve Grandcourt

(Photographs by courtesy of Journal of Esperim

I N considering the significance of the study of arti-ficiality grown connective tissue as it applies to the problems of development and decay, it is well to keep in mind that this is the supporting tissue of the body; the other fundamental tissues being two in number— the size from which the skin and nerves develop, and the one which makes up the gastro-lightenial tract and the

gastro-intestinal tract and the organs which have to do with supplying food and oxygen to the body.

The function of connective tissue is not uniform. It comprises bone, cartilage, ligaments, etc. From it, also, is grown the network through which the lymph The cells in this network are en dowed with special properties of growth and play a most important rôle in bring-ing about repair when tissue is injured; they, in fact, form the scar in the wound.

texture of connective tissue varies; it may be in whole or in part composed of fibers or elastin, or its structure may be consistently intracellular. Occasionally, the erance of elastin in the fib verts it into true elastic tissue, significant of its mechanical adaptation.

Approximately three quarters of a cen

the origin of tissue was definitely as by Schielden and Swann to be the work done (in proce of division) by the individual cell. Brown had already discovered the cell nucleus, and Wagner had said the

egg was only a cell. Claude Bernard m made known the law that forms starting point of Carrel's investigations, i. e., that the life of an organism is dependent upon the interactions of its cells and of the medium in which they grow, or its cease and or the menum in which they grow.

Thus the problem of understanding the means by which
the body develops, and why it must undergo (at least
in our present state of knowledge) more or less early
deterioration and death, resolved itself into learning the character of these interactions. This was obviously imoutside the body, and so making the process suscentible

Carrel's first efforts after his success in keeping these

Carrie's first efforts after his success in keeping these insense in a state of indefinite multiplication ("permanent life") were directed to studying the manner in which the medium affects the life of the cells. The earliest medium was specially prepared blood (plasma) from full-grown dego or chickens. It was soon apparent that the older the animal from which the blood was taken, the less rapidly and extensively the times grew in it, while in the blood of the relatively defined in the present man are subther the sense of the contraction of the sense of the contraction. old animal, the increase became so slight as to be prac-

Comparative experiments were then made between the effects of the plasma of animals whose ages were respectively five months and five years. The results showed enormously greater activity on the part of the blood of the growing animal, the rate being sometimes haif us much again.

The conclusion reached was that when an animal attains its size (that is, when its tissue stops growing), its blood undergoes progressive changes until it lacks more and more and at last nearly all of the dynamic

Now, the question was whether the old plasms could be given the force of the young, so far as its activity

5. Seventy-two-hour growth (after be 1 168 times through salt solution and was

Office Market Contract Contrac

on growing cells was concerned. This was accomplished by mixing it with juices extracted from the embryo. When the plasma of young animals was modiembryo fied in the same way, a greater proportional increase in its activating power resulted. In this connection an

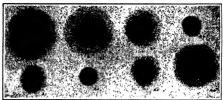

Fig. 1.—Showing comparative rate-growth of tissue respectively in plasma

 $A^1$  and  $A^2$  grown in plasms,  $B^1$  and  $B^2$  in mixed medium. In  $A^2$  and  $A^4$  and  $B^3$  and  $B^4$  the conditions were reversed.

interesting series of experiments was made with a strain of connective-tissue cells which had been kept in artificial life for more than sixteen months

It was divided into two parts, A and B; A being grown in adult plasma, while B was pisced in a medium composed of two parts plasma and one part em-In two days, the ring of new tissue around B was three times greater than that around A.

The cultures were then washed in sail solution (this

Fig. 2.—Seven-day incubator growth.

particular process being the condition of their "per manent life"), and the experiment was repeated. I grew practically at the previous rate, but A was sta tionary. (See Fig. 1)

Tissue passed through salt solution 130 times doubled

its area in 48 hours. Another growth washed 87 times increused its volume 15 times in 10 days Still another, under special conditions, augmented "more than tifty times in slx days'

400

These rapid growths, however, could not be duplicated in normal plasma, the further modifying of which was undertaken In one case it was diluted, in un other substances were added to it, or again its reactive power was changed or its osmotic tension made greater or less By measuring the extent of the new growth accumulated between passages salt solution, it was easy to estimate the varying effects produced by the different media. The relation between the extent of the growth and the particular character of the medium was always the same

Or Carrel says: "As the rapidity of growth of a tissue depends so much on the composition of the medium, it may be come possible to use as a reagent of the dynamic value of the humors of an organism, a strain

of cells adapted to life an vitro.\* If human connective tissue cells could be preserved in a condition of permanent life, as connective tissue cells of the chicken are preserved, the value of the plasma of an individual might be appreciated by the cultivation in it of a group of these cells and by the observation of the rate of their multiplication. These observations would perhaps give some indication of certain values of the blood of an organism and possibly some clew to its age."

it became evident, in the course of experiment, that the activity of tissues was apt to vary, alike in the same lody and in their own parts. Was each particular condition permanent, or did the dynamics of the cells change through the action of the medium upon them?

To determine this point, several pieces of tissue, each having its own peculiar dynamic power, were cultivated in media exactly allke. For a time, differences in the character and extent of the growth were marked. Then the influence of the medium began to tell Measure-ment of changes undergone on the part, in turn of a fast and of a slow growing tissue, showed that the former had lowered its activity one half in forty eight hours, while in the same length of time, the latter had multiplied its activity by six. This process continued until the level of uniformity was reached when the conditions of growth remained equal in all cases

Therefore it was evident that though in the begin-

ning certain substances which the tissue had accumulated had the offect of accelerating or retarding (as the case might be) its activity in the medium, yet in the course of lime, the medium operated to overcome these conditions and bring the growth under the laws of its own special mechanis

Further experiments were tried, some with cells whose growth was stationary Results all pointed to the same

Thus the sum of investigations on the influence of (Concluded on page 420)

# The Mobile Army of the United States

# Its Organization. Equipment and Method of Operations

By a Major of the United States Army

T 1E Regular Army of the United States in time of neace consists of thirty regiment of infautry, fifteen regiments of cavalry, six regiments of field artillery, and the coast artillery, together with the various auxillary troops and shiff departments. The auxiliary troop comprise the engineer, signal and sanitary troops. The staff departments are the General Staff Corps, the Adjutant General's, Inspector General's, Judge Advocate General's, and Ordnance Departments; Quartermaster, Medical, and Signal Corps; the Corps of Englneers; and the Bureau of Insular Affairs. In addition there are the Professors of the Military Academy. The Philippine Scouts and the Porto Rico Regiment of In-

Philippine Scotts and the Fore Rice Regalact of in-fairty are also a part of the Regular Army. The Infairty, cavalry, and field artillory, together with the proper proportions of auxiliary troops and of the stuff departments, compose the Mobile Army which is available at any time for service in the field, that is anywhere it may be desirable to send them. These are the troops which would be organized into armies

to invade a foreign country or to repel invasion.

The Coast Artillery Corps is a technical arm specially trained to handle the large cannon and the submartice mines intended to prevent a hostile navy from entering our harbors and capturing our seaconst cities, naval ing our harbors and capturing our seacostic cities, nawa, stations and depots of suppiles. Those troops are trained to a certain extent as infantry and might be so used in an emergency. As, however, their special work is too technical to perant of their being readily replaced, and as their withdrawal would require that the navy should remain at home to protect our ports rather than to seek the enemy's navy, knowing that it had a secure base behind it, the use of Coast Artillery us part of the Mobile Army cannot be relied upon. The present strength of the Coast Artillery is about 800 officers and 15,000 cubisted men. The men are armed with the infantry rifle, and, as previously explained, are drilled to a certain extent as infaniry

The Philippine Scouts are recruited from the natives of the Philippine Islands. The company officers are mostly Americans, principally ex-non-commissioned officers of the regular army. There are a few mative con pany officers. The senior officers are officers of the regular army, specially detailed for this duty. The present strength is about 5,000 officers and culisted men

The Porto Rico regiment of infantry consists of two attailous of four companies each. The officers are battallons of four companies each. The officers are obtained in the same way as for the Philippine scouts, and the callsted men are all natives of Porto Rico.

The mobile army is organized into four divisions and a cavairy division. Of these troops, three divisions and the cavairy division are within the territorial limits of the United Sintes, except such troops as are in the Hawalian Islands, Alaska, and Panama. The other division is in the Philippine Islands

The company, the troop, or the battery, depending on the branch of the service, is the basis of organization. that is, the samilest tactical and administrative unit The infantry company consists of one captain, one first The intantry company consists or one capcain, one has and one second fluitenant, and seventy-five enlisted men. This is the peace strength. The men are now supplied with the newest prescribed equipment, and are thoroughly ready for effective field service.

The troop, the smallest cavalry unit for administrative purposes, is commanded by a captain, assisted by one first and one second lleutenant, and has an enlisted peace strength of slaty-live men. The men are armed with the rifle, pistol and saler, and are trained to fight elther on foot or mounted

buttery is the smallest administrative and tactical unit of the field artillery. It is commanded by a captain, assisted by two first and two second Beutenants, and on a peace footing has an emisted strength of one hundred and thirty-three men. Each battery is charged with the bondling of four gans, either light (3-luch) or monutain (207-luch). Ammunition for the light batteries is carried in calesons, each drawn by a team of six horses. Amountition for the monolain vell us the gaus themselves, is carried on pack mules. The officers, non-commissioned officers and a few specialists only are mounted, the remainder of the command travels on foot. In the light batteries the entire command rides. Officers, non-commissioned officed drivers and certain specialists are horsed. These noneers all ride on the carriages. The weight behind each team horse amounts to about one thousand pounds. Compared to lands behind draft horses to civil life this does not appear to be much of a load, but it must b remembered that at certain times high speed is required of the artillery animals, not to speak of poor rands, broken country and other difficulties seldom met with

in ordinary commercial traffic.

When taking to the field, each company and each troop is supplied with one escort wagon drawn by four mules. Each battery is furnished with four such vagons, two drawn by horses from the battery and two es. All wagons and all mules are the property of the Ouartermaster Corps of the Army.

We have touched in a general way on the smallest tactical units of the service. There exist in addition the Engineer, Signal and Sanitary troops.

These troops are all organized into companies and battations. The engineer troops are charged with ploneer work, such as road repairing, repair of bridges, clearing away of obstructions in the nature of wire entanglements, blocked roads, etc., as well as the transnds, etc., as well as the tran portation and use of bridge material for the construction of pouloon bridges. The actual construction of trenches and other light field works is the task of the troops that will use them, but in cases of slege or slege erations, the engineer troops aided by civilian lab will have entire control of the execution of the work.

Communication between the larger elements of a

command from Army Headquarters through the divi es is maintained by the Signal Corps troups, by means of wireless telegraph, ordinary telegraph, telephones, hanterns, rockets, etc. This work is technical as well as tactical, and has been brought to a very high state of efficiency. The instruments in common use are excellent in character and of a kind thoroughly suited to field work

The saultary troops are distributed an

ous regiments of infantry, cavalry and field artillery. Their duties pertain to the battle field. Besides those se detailed there are ambulance communies and field inspitals, controlled by the Medical Corps, for the trans-portation and care of the wounded after first aid has n administered at the regimental dressing static

From the companies, troops, and batteries we advance to the buttillon and squadren. The infinitry battallon includes four companies and is the command of a major, assisted by his staff—one adjutant, one quarter muster (both lieutenants). The cavalry troops are or gunized into squadrons of four troops, commanded by a major with the same staff officers as the infantry bat-talion. The artillery buttalion embraces three batteries. The battalion and squadron are merely tactical (fight-

Battalions and squadrons are groused into regiments lu the infantry and cavalry three battalions or three squadrons, while in the field artillery two battalions make a regiment. Regiments have a distinct designa-tion, and are permanent organizations. Each regimen is commanded by a colonel, assisted by the fleutenant-colonel and the regimental staff, consisting of one adjutant and two supply officers. Each regiment of in-fentry and cavalry has its own machine gun company armed with four Colt muchine guns. To each regiment is assigned a chaplain, medical officers and a

The regiments are further grouped into brigades of infantry, cavalry or field artillery for tactical purposes minutry, eavairy or neid artiliery for tactical jumposes, thrigades normally cousids of but one branch of the ser-vice, so that they are spoken of as infantry brigades, cavalry brigades, etc. A brigade is the command of a brigadier general. He is allowed a brigade adjutant with rank of major, and two aids, with the rank of

These brigades are in turn grouped to form the divirives intrances are in turn grouped to form the offi-sion. A division is normally organized as follows: One major general, commanding; his staff, constating of one chief of staff (colonel), one assistant chief of staff (major or captain), one adjutant (major), one impretor (major), one judge advocate (major), one quarter-master (lieutemant-colonel), one division surgeon (lieutenant-colonel), three aids (captains or fleutenants). tenant-cooner), three and conyams or neutranats). Communitors of the engineer and signal troops may required to serve at division headquarters in the capacity of division engineer and division signal officer. The fighting forces and their auxiliaries are as follows: Three brigades (infantry), one regiment of cavery, one brigade of field artillery, one pioneer battalion of englancers, one field battalion of signal troops, four ambulance companies, four field hospitals; also for purposes of supply; one ammunition train, one, supply train

or supply: one stammation train, one, supply train (wagons), one pack train. The organisation of a division is the result of long years of experience, both in this country and abread. It is the one force that might be said to be rounded out. It is the one force that might be said to be countried.

It is featly a small army of about twenty thousand
men, and is self-sustaining. The infantry is the preponderating force, naturally, for infantry bears

brunt of every battle. No enemy can be shet sat of a position. In the final period of an attack that which brings success or failure is the ability of the infants? te gain hand to hand contact with the defenders, size situting fremendous loss of life. This contact may t literally come to pass, but the desire and the willing ness to gain it must exist in such degree that the

ess to gain it muse values with mem will resize it. A command composed of two or more divisions with omplements of heavy and siege artilitery, bridge trains, and the an additional force of infantry and cavalry, a sary supply and ansmunition columns. co a field army and is the appropriate command of a lieu-tenant general. A field army is designated numerically. A command composed of two or more field armies con stitutes an army. It receives a territorial designation and is the appropriate command of a general. Field armies and armies are created only by authority of the

en an army, field army or division moves again a hostile army, or against some other objective, it operates from a base. The line joining the army and this base is called the line of communications. As the ny advances, sufficient force must be left to go

The army is preceded by its cavalry, which keeps a day, or even as much as three days' mare forming a screen for the purpose of warding off efforts of the opposing force to gain information, and at the and gain information. This cavalry acti and gain information. This cavalry acting alone, some-times accompanied by artillery, is called the Independent Cavairy. Behind the Independent Cavairy come the Advance Cavairy. This cavairy operates in group from the size of a patrol of from four to eight troe to a troop itself, and is used for the purpose of stree ening the screen at vital points, and to reconnector dis-tant points that forces of the enemy may have become lodged in, in order by such reconnaissance to prevent urprise of the main body.

At a distance of several miles from this advance

At a distance or several muse from this avvance cavilry marches the Advance Guard composed of infan-try and field artillier, and behind the Advance Guard the Main Body, composed of the great bulk of the troops, followed by the trains and finally the Bear The flanks are protected by Flank Guards or

In a large command the size of an army, one read of course would not accommodate the force and enable it to be placed in action to the front within a reasonable time to be serviceable. Hence, with such a command, several parallel roads would have to be used for the advance, each field army having its own. When an army moves in such formation, the independent cavalry still remains under the direction of the supre mander, but each force on the separate roads would control its own advance cavalry, advance guard, etc.

Communication between columns would be maintained
by contact patrols, bodies of troops detailed for such

Durpose.

The independent cavalry having gained information of a vital nature, the advance is continued for the purpose of gaining contact. The advance cavalry may at this point merge into the independent cavairy. Though not necessarily. Later the advance guard comes into the action with its infantry and field guns, occupies the position seized and held by the advance cavairy, which withdraws, while the action is developed by bringing up reinforcements. Usually when the reserve ce guard goes into action, the artillery is of the advance guart goes no action, the archivery is committed also. It begins its firing at ranges of from two to three thoushed or even four thousand yards. In an advance of this kind, the object is to sentime, and the problem resolves fissif into driving the enemy from his position, either by actual force or strategy. In the former case, it is vital to get as close to the enemy as possible. It has been stated before that an enemy cannot be shot out of a position; he must be driven out at the point of the hayonet, or at teest, the morale of the housile force most he so lowered that when hand to hand fighting becomes framinent at will fall back. To accomplish this the artitlery is breught utrensity into play. Its function is to silectes the hostile artillery. If this cannot be disk, it insue, newertheless neutralise the hostile artillery is by drawing its to itself and away from the shwaring timinger. In addition, as the attacking tributary size efficits the was of affective hostile infantly due, this little is the most of affective hostile infantly due, the little is the standing force may advance. The artitlery has hapeders, a very important past to play, for the satisfer hold in his proportant. ot be shot out of a position; he must be

# discounties consect choice. Influency in these days actually in shall groups, so that with come are moving formed the health greatly, the first come are moving formed the health postline, these constitutes stationary that the section chief to prove chaines that the section chief to greater chaines there is not the section with the ground chaines there is that the section in the greater chaines there is not the section of t rune, ann is eas expressed that troops have arrived at the heafth like enthrily suchanished and opposed by such five action that the sending of reinforcements has been preclicitly impossible. But if the artillery of the at-cellular army has been in sufficient force to allence or respiration bestile artitlery fire, and to sid in keeping the heatile infantry well down behind their trenches, in own infantry should eventually arrive at the enemy's spointfeld well able to drive home the final attack. Before

when the enemy is driven out, the cavalry which at the commencement of the battle is held on the figures for emergencies is rushed in to complete the rout and

sponition well able to drive home the final attack. Before this dual attack, bayonets are fixed and the position is then eareted as in encient days by the personal valor off the individual soldier, using his gun as a spear or

for emergences in reserve in the control of the courty on the pursuit.

The infantry and cavalry are armed with the Spring-eled rife, to which may be attached a bayonst. The bayonst is insued to the infantryman only. The cavalry-

man has instead a revolver and sales.

The Springfield (or United States) rifle is a 0.30 caliber rifle manufactured at the Springfield Agreenal. It has a steel barrel twenty-four inches long, the rifling as none a scene serves twenty-rour means ong, the rining baside consisting of four plain grooves obod of an inch deep, the grooves being somewhat wider than the bands, and having a uniform twist. The barrel is incased in wood and held to the stock by means of steel bands. It contains a magazine bolding five rounds of ammunition. The magazine can be filled and locked and the rife carried in this position in perfect safety. When it is desired to fire, the magazine may readily be unlocked and the rifle by one operation of the breech-bo loaded and cocked. This rifle is capable of being fire 10 to 15 times per minute, depending on the degree of training and experience of the person firing it.

The bayonet is of forged steel, sharpened the entire length of the lower edge and for five luches back from the point on the upper edge. This weapon can be used

or thrusting or cutting.

The 8-inch rifle with which the field artillery is sipped is a built-up gun of nickel steel, of the lo-coll type. It consists of a tube, jacket, locking-he and citip, assembled and mounted on a cradle in which the recoil mechanism is held. This cradle is in turn attached to a rocker which connects the upper parts e carriage. Part of the recoil is taken up by a cylinder filled with oil, part by means of steel springs surrounding the cylinder inside the cradle, and part along the trail which engages in the ground by means of a spade. After the first shot or two the gun car remains practically stationary. The carriage is equ with a panoramic sight and quadrant for firing over a mask such as a hill or other obstruction.

The rate of fire is about ten rounds per minute. The unition is "fixed," that is, the projectile is fitt into a cartridge case of brass containing the powder charge and primer. This gun fires shrapnel and high explosive shell.

The present strength of the mobile army is about sixty-five thousand men. This force would be increased in time of war, first by calling in the regular army reserves—a few thousand men; second, by enlisting the different organisations up to their war strength with en. This would give a regular mob of about eighty-five thousand. A further increase would be made by calling for volunteers, a practice with which the American people are familiar. These would come, the anergan popular terminal. After the control of first, from the organised militia, a body of partially trained isen about one bundred thousand strong; and second, from the mess of the people, totally untrained. If the volunteers did not furnish sufficient seen, resort would be lad, as in the civil war, to consertpiton.

Mending Collulaid

To Hill immense variety of articles unde of celluloid
for demestic and personal uses gives value to a
simple recipe for mending such articles when broken.
This consists in dissoving fragments of celluloid in
incetons, applying the nesetting solution to the broken
edges like give and then pressing them long-ther. The
solution is made in a few minutes and "dries" or hardease within a quarter of an hour. If pastly done it is
aliant, impossible to detect the location of the break.
The solution of the pression of the continue of the
deligible. This solution may easily be twisted any
desirable finded thes.

# Sterilizing Water by Ultra-Violet Rays

To the Editor of the Schriffic American:
We note that you have published on November 1st, page 336, an article on Ultra-violet Rays. In this article regret to have discovered some errors, which we beg you to rectify in your next number.

Your description of the competitive tests in Marsellies, as well as the picture of the apparatus which you give on that same page, leads the reader to believe that the apparatus tested in Marseilles, and shown in the figure, apparatus esteed in survenies, an shown in the latter, was the apparatus of Courmont-Nogier. I refer you to the Comptes Rendus of the French Academy of Science, October 17th, 1910, where this apparatus has been described by Messra, Henry, Helbromers, and Recklinghausen. I also refer you to the official report of the Municipal Water Commission of Marsellies, page 57, where it is said that the apparatus was of the system of Mesers, Henri, Helbronn er, and Recklinghausen

I suppose i need not go into the question of patents which only confirm that the apparatus shown in your publication and put on trial during the famous Mar-seilles test was of the system of which the undersigned MAX VON RECKLINGHAUSEN

New York city.

# Are Men Better Typists than Women?

To the Editor of the SCIENTIFIC AMERICAN The very interesting and timely article in your edition of October 25th, by Jacques Boyer, bearing on scien tific tests to prove whether men or women make the most efficient typists, has won my attention, as the greater part of my life has been devoted to teaching both boys and girls the art of properly manipulating the typewriting machine.

Naturally, from my standpoint, an argument must ome from the practical side of the question, for, prior to the SCIENTIFIC AMERICAN'S publishing that tests have been made by scientists with instruments, the real depth of the question had not been considered. Mr depth of the question had not occur considered. Set Laby, in his article which opens up so interesting a point of view, does not seem to have settled the question of the relative efficiency of the two sexes to his own satisfaction through the agency of selecutife instru-ments, for he says, in his closing paragraph.

e conclusions, however, are based upon to a number of observations to allow them to be affirmed positively and with conviction. The results here given are merely indications which may be confirmed or invalidated by future researches."

invalidated by future researches."
It is not my purpose to endeavor to invalidate the researches written of by M. Boyer, but at the same time I may be able to present a few points on the practicability of typists in general which may be intresting to the SCENTIFIC AMERICAN and help to Himminate e of the dark spots which the scientists have falled

In determining whether men are better typists than on severenming whether men are better typists than women, the history of typisewithing and typewithing contests about be, we think, a paramount consideration Such a history has never been written, but the goment facts have been fairly well recorded in the pages of magazines devoted especially to the interests of typists and typewriters.

When typewriters were first introduced, women found a new vocation The field was at first somewhat evenly divided between the sexes, but of late years women almost wholly displaced the men in this line of Is not this fact in itself an indication of the survival of the fittest?

The size and shape of the hands and fir edly play an important part so far as adaptability to the use of a typewriter is concerned. If mere strength were the only requisite, then the advantage would cerwere the only requisite, tues the autanties would tainly be in favor of the men, whose fingers are generally larger and stronger than those of the women But the man with extremely large and strong fingers. But the man with extremely large and strong ingers is often at a disadvantage when operating a typewriter because the very size of his fingers makes it difficult for him to manipulate the keys. In this respect women have a distinct advantage, as their fingers are more slender and better adapted to the manipulation of the keys. Because a man has large fingers does not, kays. Because a man has large fingers does not, of course, mean that his fingers are not quick in their actions, but that they are not so well adapted to the kayboard. This is supership the cases when all the fingers of the hands are employed in striking the keys, which is the only scientific method of operating a type-writer. Some of the fintegrh shorthand writers in the world have large lands and fingers, but they almost invariably employ a woman typist when making the transcript of their shorthand notes.

As early as 1888 the Canadian Shorthand Society organized a typewriting speed contest to decide who, among the many claimants, should be entitled to the world's champlonship. This contest was held on Angust 13th, and was won by Miss Muc E Orr of New York city. One of the apponents of Miss Orr was the celebrated Frank E Mctimrin. The fact that Miss Orr defeated McGurrin and all the other aspirants for orr detented metalitin and all the other aspiralist for the title settled for many years the question of the world's champlonship and demonstrated the special aptitude of women for this class of work.

Various methods of learning the operation of the typewriter were advocated in the early days, but il was several years after the Toronto coulest before what is now known as the "touch" method became generally recognized as the only scientific way in which the high est degree of efficiency could be altained. Miss Muc Carrington wan the blindfold champleoship but was the Pan-American Exposition at Buffulo and at various conventions throughout the country, became well known as the fastest and most accurate typist in the world re must was conceded to be in the same with Miss Carrington

However, in 1905 a series of speed contests were held at the Business Show at Madison Square Garden Miss Carrington won the blindfold champlonship but was defeated by Mr. Paul Munter and Miss Rose 1, Fritz in the half-hour copying contest. in this contest there were two preliminary trial contests of five and ten minutes each, in both of which Miss Fritz was far ahead of the other contestants. In the final contest Mr Mun ter was just fifteen words uhend of Miss Fritz Had the final results included the five and ten minutes' con-tests, Miss Fritz would have won over Mr. Manter by a good margin

In 1996 Miss Fritz won the world's championship at Chicago, and in the same year successfully defended her title in contests held in Boston and New York. The Eastern Commercial Teachers' Association held a series of contests in 1906, 1907, and 1908. In all, six contests were held, three for the world's championship and three for the world's school champlouship sts were won by the gentler sex

From 1907 to the present year an unumal typewriting outest has been held in connection with the Business Show at New York for a thousand dollar trophy, representing the world's typewriting championship. This trophy was won three times in succession by Miss Rose L. Fritz, then Mr. II. O. Blaisdell won it twice in succession. In 1912 Miss Florence E. Wilson won the trophy, writing at the rate of 117 pet words a minute for one hour. This wonderful record was collesed by Miss Margaret B Owen on the 21st of October last, when she wrote at the rate of 125 net words a minu for one hour, thus whatling the trophy, and the title of world's champion typist

words changion typics. Conclusions to be of any value must be based upon correct promises. That thought came to us when rending M Lahy's article. Were the premises correct? The subjects examined by M Lahy consisted of six women and live men. The women had from two to four years' practice in typewriting, whereas the experience en ranged from two to eight years. Would not the additional years' experience of some of the men add materially to the conclusions in favor of the men? Did the investigator choose the typists because of their experience as all-round expert typics, occulied shorthand writing larve any part in ambing the selections? If a typict is enoughed only in conjung work, should his andi-tory reactions be considered in the results? Another important question which arises relates to the muchine What machine did the various typists whom M. Lahy examined use? Did they all use the same style of ma chine? Was the experience of each of these typists confined entirely to the same machine, or were some common entries to the same machine, were some famillar only with a partleiblar machine, and others famillarly with several styles? Would M. Lahy condider famillarly, with several styles an advantage or dead-vantage in making the experiments? These are only a few of the many questions which readily suggest elves to any one familiar with the work of typist from every point of view

The fact that nearly all of the world's work in this line of endeavor is in the hands of women, and that in open competition for so many years they have carried off the premier honors, seems to us to be worthy of consideration and to entitle women to be considered count. if not superior, to the opposite sex as typists

C E SMITH New York city (Author of Practical Course in Touch Typewriting)

Hudson Bay Fisheries are to be thoroughly investi-gated from a commercial standpoint by the Canadian government, as it is expected that with the opening of the Hudson Bay Railway a large fishing industry will be developed. The number of steamers entering Hudson Bay this year from the Atlantic has been the largest on record, including two which brought cargoes of pitch pine all the way from Mobile, Ala., for use at the railway terminal under construction at Port Nelson

# Labor-saving Appliances of the Modern Great Hotel

Housekeeping on a Manufacturing Scale. Where Mechanical Devices are Used for Everything, from the Boiling of an Egg to the Rolling of a Butter Ball

By Joseph B. Baker

THE running of a modern great hotel is something The running of a nodern great hotel is something more than housekeeping on a gigantic scale: It partakes of the nature of a manufacturing business. The volume of work involved in providing eighteen or twenty hundred guests with food, louding and entertainment makes simplified methods as necessary as systematized management. The operation of a reserved aurant or ordinary large hotel is generally like do housekeeping magnified. The proprietor needs as much room as possible for tables, that pay revenue, and the cramped space allotted to the kitchen is crowded with cooks and dishwashers and hurrying waiters with perhaps here and there a time-saving appliance tucked away in a corner But In the great hotel radically different methods must be employed. The army of hotel servants, the great store of supplies, the intensely active business that goes on in the underworld of the hotel imperatively requires space and therefore allows room also for the installation of mechanical

aids in speeding up the work.

In the conduct of the hotel the ideal is to approximate the service and atmosphere of the well-ordered home—It is to help attain this ideal that special machines or convey a case that the total that special inachines or devices are to be employed. Incidentally such appliances must justify the room they occupy and the capital invested in them by doing the thing, wh tever it may be, with efficiency and economy comparing favorably with the ordinary methods.

The ampliances that are activative and activative and the contractive activative and the contractive activative activati

The appliances that are actually used to meet this need are of three general classes, according as the economy effected is primarily a saving of time, labor seconomy elected is primarily a saving of time, tabor or material Many appliances which save time pri-marily are found in the food-service and housekeeping departments of the hotel. The automatic egg boiler, actuated by clockwork (driven by a lead weight) or a small electric motor, figure largely in the serving of breakfast. This ingenious apphance is one of the few which are found in medium and large-capacity restaurants also; because it saves well-nigh 99 per cent of the time and attention connected with boiling eggs to the patron's order and occuples very little Suppose a waiter has an order for 2-minute eggs. By a single movement the operator of the operator builer places the eggs in a metal basket and lowers them into a tank of boiling water at the bottom of the apphance and sets the index at the 2-minute mark. en he can forget it, for at the expiration of the time set the eggs are lifted automatically clear of the water and a bell may be rung also to call attention. At the busy breakfast hour the gang of egg boilers is in active and their value in time saving is impressively

The slicing of bread is an opportunity for a machine to give satisfaction to guests by a uniform product in addition to saving material. As often happens where mechanical devices are employed to replace hand labor, this machine has its own way of doing the work differing from the primitive hand method, vim, by the motion of a circular knife which divides the lost by a smooth "draw cut," the loaf bong advanced not the thunkness of a slice after each cut. The cold work, differing from the primitive hand method, via. just the thickness of a slice after each cut. The cold meat slicer works on a similar principle, and its work meet sheet works on a similar principle, and its work is far more important to both guest and host, on account of the higher cost of meat. The cold meet to be silend nust be made ready by removing the lone; after that is done an inexperienced by can in a few minuser transform the joint into a pile of silene of slequid tilekness and as attractive to the given as the work of an expert carver. The weightable parer used principally for potatoes and carrots, is a striking instance of a power-driven machine which "peels" by a special method replacing the paring knife of the hand worker.

A sack of potatoes emptied into the hopper of this large machine are scraped by attrition against a revolving abrasive disk instead of by the action of a blade and come out of the machine in their original shape without waste and needing only a few touches with a knife to remove the "eyes." This machine is emmently a time saver on account of the large quantities of pota-present conditions of crowing, as arready indicated. The apple parer and corer, usually hand operated, turns out cooking apples ready for the chef and requir-ing no further attention by hand labor; removing the peel by a blade which is usually adjusted to take a deep enough out to remove surface blemlehes also, the idea being that time saving is more important than the stose boing that time saving is more impos-tion of the exceedingly thin paring obtained by hand work by the careful and thrifty housewives of a former day. Under present conditions the balance between the cost of a barrel of apples and the wages of hand workers makes the employment of a machine of this

workers makes the employment of a macnine or tain type a geniline economy.

Apart from appliances for handling food there serveral instances of time saving in the food serving and housekeeping departments of the great hotel. The telastograph ably supplements the intercom-munication service of the telephone, saving time for messages which do not require direct conversation between sender and receiver. For instance, this instru-ment is annihored to expedite the service of meals ment is employed to expedite the service of meals in the main restaurants of the hotel and also in the private apartments of guests. The written record, private apartments of guests. The written record, a reproduction of the original handwriting inscribed at the transmitting instrument, not only saves time but prevents confusion and errors in the waiters' work. In the main dining-room the waiters may give their but prevents confusion and errors in the waiter's work.
In the main dimig-room the waiters may give their
orders to an "announcer" stationed just beyond the
kitchen door. The announcer, instead of calling out
the order (as is ordinarily done) picks up the pen of
the telautograph and writes it legibly for transmission
to a receiving instrument installed a hundred feet or
more away, under the eye of the kitchen forman.
This man tears off the messages as they come in and
hands them to the cooks and servers; so that by the
time the waiter has arrived in his turn at the service. annus them to the cooks and servers; so that by the time the waiter has arrived in his turn as the serving counter his complete order may be ready on a tray accompanied by a check. The instantaneous trans-mittal of a written record answers equally well in the serving of meals in the rooms of guests. A late riser, mittal of a written record answers equally well in the serving of meals in the rooms of guests. A late riser, for example, has only to step to his telephone and tell the branch exchange operator what he wants for breakfast—making his selection from the daily menu eard. The operator writes the order on her telautograph, and it is reproduced on one of a gang of receiving telautographs in the kitchion. The message is simultaneously reproduced on two other receiving instruments, viz., for the floor clerk for his supervision of the order, and for the floor waiter for him to get his table service ready. The time gained onables the guest a breakfast to be delivered to him in a few muntate via electric dumb—waiter. The telautograph transmits notice of a guest's departure simultaneously to several different departments of the hotel, viz., to the room clerk to inform hum that the room will shortly be available for snother guest, to the floor operate output the room may be put in order, and to the brusekeeper's office for general supervision of the makid's work. Ricetricity has an interesting application in the maked service to rooms. Every maid on coming on duty is given a numbered electric plug. On entering a guest's room to put it in order the inserts this plug

in a springjack at the door causing a little incandessent lamp to light up in the plug as a signal that a maid is at work within. The jack contact also causes a lamp to light up on the telephone operator's switchboard, informing the operator at all times as to the location of the maid; so that in case a guest calls for location of the maid; so that in case a guest calls for a maid for any special purpose the operator can send the nearest available one to her room immediately. Another circuit from the room jack causes a same to glow on a panel board in the housekeeper's office so that the housekeeper knows at all times just where and when the different maids are working just as well as though she personally visited every corridor of the

hotel. The dictograph plays an important part in saving time in the management of the hotel by enabling im-promptu conferences to be held between executive officials at any moment without calling them from their omoises at any moment without caming them from the posts. The entertainment of an army of guests requires good tactics on the part of the army of the hotel staff, and the maneuvering is greatly facilitated by the instantaneous and direct intercommunication afforded

instantaneous and direct intercommunication afforded by the distorpraph.

The telephone installation is of course the major means of communication; if may easily equal that of a good-sized central office. The largest private branch exchange in the world is now in use in a great meterophitan hotel; 16 operators' positions, each equipped with elastograph, 2000 lines and 75 central office trunks, 600,000 local messages per year in addition to many long distance calls and innumerable baside communications.

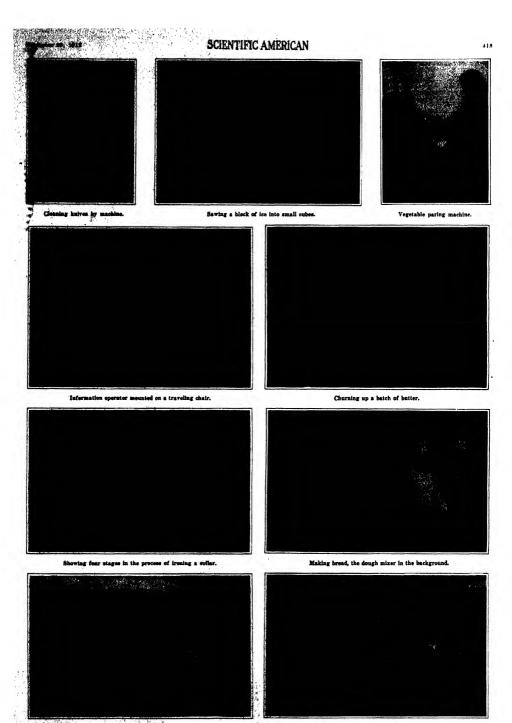

One of the most modern devices affecting the b of the "front office" of hotels is an index rack which renders possible the rapid and accurate handling of renders possible the rapid and accurate manning or information relating to gueste. The ordinary cumber-some index book, which it is absolutely impracticable to use for a very large number of arrivals and depar-tures, is dispeased with and replaced by a rack which exposes to full view at all times, and at a single glance the names and worm numbers of all the guests. By exposes to tuil view at ait times, and at a single glance the names and room numbers of all the guests. By the use of manifolded typewritten allps, made out from the loose-leaf register, this information rack is duplicated in several places so that each department, the telephone switchboard, the mail elerks, etc., have at all times a full current record of the movement of guests. An essential feature of this "unit index rack" system is that the names always appear in their correct alphabetical order, without blank spaces. It is a "live" system, the development of which has been found absolutely indispensable to the operation of the great

modern notes. The information desk, aft essential part of the man-agement of the great hotel, is the nerve center of the guest's activities, just as the manager's office is the nerve center of the hotel organization itself. The nerve center of the hotel organization itself. The information operator, rested on a traveling chaft in front of her constantly corrected index rack and equipped with telephone and telestrogenh instruments, is in position to answer any inquiry that may come in, premptly and accurately.

LABOR SAVING MACRINERY OF THE MODERN, GREAT HOTEL

# The Heavens in December

# Return of the Third Comet of 1900

By Henry Norris Russell, Ph.D.

S TILL another comet, and again a periodic one, has to be reported this month. It was first seen by Zhuner at Bamberg, Germany, on October 23rd, and wins visible in a small telescope. At that date it was in the constellation Serpens, a little south of the equator, and set atout four hours later than the Sun. As soon as its orbit was calculated it was recognized as a return of the third comet of 1900—the second return since the original discovery, but the first one obed, since in 1907 the comet and the Earth were far

The unnexed diagram of the comet's orbit will make this very clear. As usual, the part of the comer's orbit which lies above the plane of the paper, in which the planetary orbits are supposed to lie is drawn with a full line, and the part which lies below with a dotted

The inclination of the orbit is 31 degrees, and the comet's period is 6.46 years. When the comet was in perihelion at C in 1900 the Earth was at E, about eighty million miles away; and as the comet and Earth were moving around the Sun in the same direction (the comet a little the faster), the distance between the two never decreased far below this amount. In 1907, when the comet returned to C, the Earth was at E, than 160 million miles away, and on the other side of the Sun, so it is no wonder that this return was not observed. This year, when the comet came once more to C (on November 2nd) the Earth was at  $B_n$  only fifty million miles away, and the conditions for observation were very favorable. In 1920 they will obviously again be very bad, but in 1926, unless the comet's period is changed by the attraction of Jupiter,

it should come very near the Earth.

As is the case with all short-period comets, the orbit of this one passes quite near to that of Jupiter. Indeed, at the last aphelion passage of the comet, in 1910, it was pretty near Jupiter for some months, and its orbit may have been a good deal changed.

The comet's apparent motion in the skies took it

rapidly southward, so that on November 19th it was already in 30 degrees south declination, and lost to northern observers.

Of the three comets previously under observation, Metcalf's is in Capricorous in 20 hours 53 minutes right ascension and —14 degrees 20 minutes declination on November 30th, and moving 30 seconds west and 18 minutes south per day. It is then only one third as bright as at discovery, and rapidly decreasing in bright-

Neujmin's comet is now fainter than the fourteenth magnitude, and can be seen only with the large struments. Elements of its orbit, calculated at the University of California on the basis of observations envering an interval of six weeks indicate

a period of 1783 years for this remarka object, but a longer series of observations will be needed to determine the period with

Westphul's comet, on the other hand, is well placed for observation in t It is slowly receding from the Earth and Sun, but should be still a con spicuous telescopic object. The published epitemerides of its motion have already run out at the moment of writing, and no later ones have been received; but a direct calculation shows that during December the position should be as follows:

Nov 20, R A, 20° 35" Declination + 40°

Dec. 15... 20° 51" " + 48°

Dec. 31 " 21° 18" " + 56°

It moves northward and a little westward from Cygnus into Cepheus, passing about 2 degrees west of a Cygni on De-cember 9th. Ity the end of the month it is a circumpolar object visible all night long, but best in the evening

Almost nothing has yet been published concerning its uppearance or physical characteristics, but it seems to be condi-erativ minter than in 1852. In that year it reached the magnitude 4.5, and thought is a little further from the Eurth th time it ought, unless it has really faded. to be of the 5th unguitude on Decemb 1st, and easily vistble to the naked eye; white last mouth, when it should theoretic-ally have been as bright as this, it was actually far fainter and not conspicuous in a small telescope. But the brightness

of a comet is an unpredictable affair, depending larg upon its own internal activity, and usually increase at and after its perihelion passage; and this comet may therefore become visible to the naked eye after

Our map shows how the splendid group of winter constellations which centers in Orion has come fully into sight once more.

The whole southeastern quarter of the beavens is full of bright stars. Perseus and Aurisa are right overhead, and Taurus is just south of the senith. Orion and

Orbit of Zinner's comet.

Canis Major are respiendent in the southeast, and Gemini and Canis Minor in the east. Below the latter rises the head of Hydra, and the "sickle" of Leo is in sight farther north.

sight farther north.

Between these and Gemini is the inconspicuous group of Cancer, remarkable only for the star-cluster ceiled of Cancer, remarkable only for the star-cluster ceiled of Cancer, remarkable only for the star-cluster ceiled only for the star of the cluster are moving together in the star of the cluster are moving together in the heavens, very slowly; and recent measures by Schwarzschild at Potedium show that they are receding from the Earth at the relatively rapid rate of 36 kilometers per second. It seems likely, though not certain, that this second, it is easier likely, though not certain, that this and at the same direction and at the same rate as the Haydes group in Tharms, in which case its distance must be a little over 500 light varies, and the star of the star of the same direction of the same form of the same direction of the same direction of the same direction. years, and the brighter stars in it must be about equal to Sirius in real luminosity.

In the circumpolar sky we find Ussa Major coming up in the northeast, Draco and Ursa Minor below the Pole, and Cepheus and Cassiopsia on the left. The great square of Pegasus stands on one corner in the

# The Greatest Side-wheel Steamer Afloat

The "Seeandbee," Latest of the Large Lake Passenger Steamers

So great is the interest aroused by the remarkably rapid increase in dimensions of the ocean liners. that the public is apt to overlook the fact that a pro that the public is apt to overlook the fact that a pro-portionate growth has been taking place in the size, speed, and inxurious accommodations of those fine ves-sule which ply upon the initiand waters of the United States. It is a fact, however, that the largest steam-ers of that excellent fieer of ships which serves the various ports on the shores of the Great Lakes, have reached a size which twenty-fire years ago was the limit for occar-going steamers, and beyond which in those days it was considered to be unlikely that the ship overse and able builder would care to go. ship owner and ship builder would care to go.

Although the "Secaudbee," which was built for the Buffalo and Cleveland Transit Company of Cleveland, is destined only for lake service, it must be admitted that, with her high freeboard, great length and imthat, with her high freehoard, great length and impeding array of four annotestach, she has very much of an ocean-going look about her. As a matter of fact, he would be inerfectly well able to take her piace, so far as see worthy qualities are concerned, in the fransitation service. This fine vessel, which was built on the lates by the Derroit Shipbentiding Company, to SOO feet in length over all, SO feet beaut, 1974 inches 500 feet in length over all, 58 feet beam, 67.5 inches wide over the guards, and her engines of 12000 horse-power are capable of driving the ship at a speed of 22 miles per hour. The hall is built entirely of steel, with a double bottom thang feet in depth extending for 85 feet of her length. The hall above the double bottom is divided by eleven attractable where the steel of the same deet, With the exception of the collision buthheads and other built-heads with trace 'sentited by the year to the head to the same feet, with heads that are required by law to be without openings, all these bulkheads are fitted with water-tight doors, sperated hydraulically from the engine room. Including

perated hydraulically from the engine room. Incinding its tank tope there are seven decks in all. An expellent flature of the vissel is the fact that the deed construction of the whip is carried up to the community deck, and the housings on the orton and sain decks and the top sides or the promence decks again decks and the top sides or the promence decks again decks and output and output sides of the proment. does. on the average power rate of five cents a kilowatt hour and include interest on the investment charged at 6 per cent, deprecia-tion of the machinery at 10 per cent, and

We must remember that these co er both the price of the hired man and his keep. Though it will be discovered that some of the machines in the tests are of large capacity, it was discovered in check-ing by tests of smaller machines of the same kind that the variation in unit cost that is per bushel or ton-was very slight.

It is needless for me to enumerate the many advantages accrued by using elec-tric power, as they are well known to most of us. However, there is one advantage However, there is one advantage of us. However, there is one advantage which the farmer appreciates more than any one cise, and that is the saving in time and lahor. The labor problem on the farm to-day is almost as vital us the maintenance of the fertility of the soil, and every labor-saving device is greeted

with open arms by the farmer.

Although this new field for electricity is yet in its infancy, the time is not far dis-tant when every well-populated farming district will have its transmission lines, for the distribution of electricity for light and power.

# Meteorological Stations in Venezuela

THE Venezuelan government has de-THE Venezueian government nas ca-creed the establishment of meteorologi-cal stations at Merida, Cludad Bolivar, Maracaibo, and Calaboso. This is note-worthy for the reason that aside from the Observatorio Caggal at Caracas there are, at present, no regular meteorologica stations in Venezuela, which is, climato logically, one of the least known countries in the world.

# Mechanical Loaders for Motor Trucks

Editor of Motor Truck Department:

In view of the tremendous interest in and-and-clay roads now in North Carolina and doubtless throughout the South Atlan-tic States, I write to ask if there is any effectual sand dumping truck-motor truck-which is also supplied with an applience to load it with something like the same facility with which it may be unloaded. I have been in correspond tion of a dumping motor truck, but, so far as I am advised, there is no machine which can load itself with the same power that runs it nor is there any separate companion machine to do this work. On the contrary, even the send dumping mechine that is described to me, which gets clear of its load so easily, must be loaded by the clumsy and expensive method of she ing it in by hand of day laborers.

In the construction of railroads now and digging of canals they have machines which load flat cars with dirt and debris almost as quickly as they are unloaded It seems to me that a machine may be de vised on the same principle, but of some-what different construction, which would scoop up the sand with such facility as to make the loading of the truck a matter of all expense and time.

If such a machine is put on the market and properly demonstrated in the places where it is needed, as for example in forty counties in North Carolina, there is prac-tically no end to the amount of business that might be done by the enterprising company which put them on the market. There is now an unexampled wave of interest in road building, and this interest is centered in the sand-and-clay road of eastern and central North Carolina, and on the South Atlantic and Guif. Experi ments are being conducted in almost every county and sand-and-clay roads are ed by many experts to be the best il purposes. W. J. PERLE. for all purposes.

[A machine such as this was de in the SCIENTIFIC AMERICAN of July 28th,

# Determining Coasting Ability of Electric Commercial Vehicles

I is a fairly well established fact that the operators of electric commercial ve-hicles are prone to run with the power on a good part of the time when the momen-tum of the vehicle would carry it a consid-erable distance without power, thus effect-That this fact is recognised in rail rond work is emphasized by the action of the engineers of the Hudson tubes between New York city and New Jersey, where meters have been fitted to the cars to ascertain exactly the ratio between the time run under power and the time run without nower. Motormen are encouraged to coast as much as possible without upsetting their running schedules by the offer of ionuses for records of coasting in excess of a standard set by the engineer, and it is understood that the method has resulted in a material saving in operating expense. By way of applying the same principle of economy to electric commercial vehicles a prominent New York firm recently has placed upon the matries a device design of the proposed of t es for records of coasting in exc expense. By way of applying the same principle of economy to electric counterparts of the principle of the number of railes with the power or and conditions are associately favorable. The derive itself is extremely simple; it underly facilities for associately favorable or consists of nothing more completed than an ordinary electric granter operator operated in the unual manner from one of the frict wheels a conclusion is of encodinged in the predicting facilities for associated of the validic. Instead of a study over of The lines, builties the master has been experiented for the principle of the principl

ber of miles covered by the vel-other row registers only the miles covered with the current the number of miles coaste words. As a concrete example of ation of the device, it is polithe makers that a 34-ton el York city without aerious attempt part of the driver to coast showed ing percentage of 20. When the s hicle was driven over the same ro the advantage of every opports coast was taken, it was fo coasting percentage had be an integrating wattmeter discient the saving in consumption of the run over the first run was exactly 11.1 pe cent despite the fact that the exverse speed of the two runs was approximat

# Vaporizing Kerosene by Partial Combustion

THE use of kerosene as fuel in and ternal combustion motor of the mes vehicle type presents difficulties so mi and so serious that though for ye erable efforts have been made to o ome them, very little of real practical value was accomplished until the neo-sary stimulus was furnished by the abnmal increase in the price of gasoline, may be remarked that carbursters feeding kerosene to motors running at practically constant speed are compara-tively easy to produce, and there are not a few that are capable of giving satisfac-tory results; but it is a much more difficult problem to supply a proper mixture at all times to a motor that jumps in a few seconds from minimum to maximum speed and power, and as quickly jumps back, and must run smoothly and sweeth

The majority of those who have attacked The majority of those who havestracked the kerosene carbureter problem have belonged to two broad classes. One has worked along the general lines already well established for the construction of gasoline carbureters, though varying the details somewhat and—what is the chiefconsideration-adding considerable heat from the exhaust gases to further vapori-sation. The other class has worked to sation. The other case has worked to some extent along gas-producer lines, subjecting ferosease, after vaportisation in a carbureter skin to a gasoline carbureter, to a high temperature and so producing aga differing very considerably from the vapor formed in a carbureter of the conventional ferois. ventional type.

Both these forms of apparatus are open to the objection that they depend upon external heat for their operation; there-fore the motor must be started first on gasoline and run on gasoline until sufficiently heated to permit the turning on of the heavier fuel. This entails a com-plete gasoline outlit in addition to the kerosene apparatus. In the carburetes type the vapor produced is easily con-densed by contact with cold surfaces, and it is not always an easy matter to avoid smoke, smell and sooty deposit in the cyl-inders. In the producer type the regulation of heat presents a rather nice pr lem, for while too low a temperature will produce a raw mixture that will not burn

which projects a spark ping in we cantiling a wire genus screen, or significated; proteons the only outlet the chamber, which is piped to the sign of the motor. Part of the kerosene sign by the spark ping and a constant the maintaining in the stream of vapor operation; a re through the chamber by the sucof the engine. The acreen prevents passage of the finne from the vicinity me ping. Approximately one per cent is known to consumed in ministrati-tion finms; the oil is not actually gastthe and is not at all hot when mixed with proper volume of air for complete com-

The varor emerging from the outlet (air Seminare is employed in place of suction to seminare in employed in place of suction purposes) is white and . like thick spoke or steam; it is Mintly warm and will not condense on magasty warm and will not consense on 886 hand. It floats about in the air with persistence. Finely stomized oil con-denses instantly on the hand and does not remain in the air for any appreciable time. Ignited with a match at a little distance from the pipe, the vapor burns with a suick puff and leaves no smoke or smell Atomised kerosene unde r the same conditions makes a dense smoke and leaves black particles floating in the air.

A wide-mouthed quart bottle filled with waper stood open for fifteen minutes, actual time, before the vapor became difficult to see; the bottle was cold when filled. The bottle was filled with vapor, the mouth partly closed, a small amount of air admitted and a match applied, when the mixture burned with a slight puff, leaving the bottle perfectly clean and making no smoke or smell. Repeating this experiment about ten times failed to canno any deposit in the bottle, though obviously the mixture was far from correct for com plete combustion.

As it is difficult to condense the vapor. even on cold surfaces, and as it seems to burn clean when even gasoline vapor would amoke, it would appear well suited to burning in a motor, and experiments with a number of motors in automobiles of different types and sises have been made with parallel results. A gasoline motor with a carbureter of this type will start, when perfectly cold, at least as easily as on gasoline. The only way in which it is possible to cause smoke or smell from the fuel is to temporarily extinguish the curbureter flame and permit raw atomized kerosene to pass to the en-gine, when the familiar black smoke will be emitted. With the carburater function ing normally the exhaust is sufficiently clean so that a handkerchief held close to the exhaust pipe will not be marked, unless by lubricating oil. Misfiring will cause the unburned charge to be passed out through the exhaust, whence it will emerge as a clean white vapor which floats in the air for a time before becoming dissipated. Combustion in the motor apper-ently is slightly less rapid than that of line: the motor runs more smoothly and can be throttled to a slower speed and holds its power better when throttled. In the tests so far made the average power has been above that of gaseline in the same motors. Carburation is not affected by sudden changes of speed. The mileage per gallon has been much higher than with machine to cases more than doub

# or Truck Queries and Answers

Mother Truck Queetes and American values of the control of the con

heavy. The idea who to A. We have had occasion to answer
increases with a sunth religion of
the nature several times, and
these the statistics a space, but sends in several attention has led us to the
spitials that every motor truch installamatters is whon groups series, or
to of the size of the one that you conmatter than the several to be services of a priremains warrants the services or a private staff of repair men and the erection of a private garage. It is probable that several of your trucks—if not all—will be several of your trucks—if not all—will be of the same make, and it would therefore or the same make, and it would therefore be well for you to engage the services of an expert from that factory as inspector or chief repair man. If you employ men as drivers who are intelligent and careful, it is possible that this one factor; expert and an assistant can attend to all of the necessary repairs, replacements and inspections, leaving the washing and cleaning to the services of a man who would not naturally receive as his tions with which are included fuel, and water replenishments—you should arrange to have each vehicle overhauled thoroughly at the end of every six or eight thousand miles. This will keep your fleet in perfect condition, and yet is work that can be accomplished without overtaxing the facilities of your repair organisation. The work will be better done than would be the case were the cars left to the tender mercies of the public garage. for your men will learn the puole garage, for your men will learn the peculiar re-quirements and adjustments of each truck, and the saving in expense will be consid-erable. If you go about the installation of your motor service in the manner that you indicate, we feel certain that it wil prove to be an unqualified success. The erection of a private garage has been found to be economical whenever more than three trucks are to be used same concern. We would urge this one point, however: When building your gar-age, plan for the accommodation of double your intended purchase of trucks, for you will find your installation so efficient and profitable that your business will increase to the point where the extra fleet will soon be required.

> P. L. M. writes: "I have a dairy busi ness in which I now use six horses and wagons for the retail deliveries. In or der to improve the service in one of the districts covered by three of these wagons, I want to put on a truck. I expect to drive this myself, and would like to know if you think a gasoline truck would prove economical. I drive in seven miles before economical. I drive in seven miles before I make my first deliveries, and the stops average about ten to a block."

> A. The retail milk business is one of the very few fields in which the gasoline truck does not always prove an unqualified success. The frequency of the stops permits only a short distance to be covered by each vehicle, and the truck is not therefore given an opportunity to be oper-ated to its full ability. Furthermore, the average driver will leave the motor run-ning during the minute or so required for and during the minute or so required for each delivery, and this may total more than the time during which the car is in operation. This will naturally result in a waste of fuel and oil and will seriously interfere with the maximum efficiency that can be obtained from the truck. Your case is somewhat different, however, you will run seven miles before you will have occasion to stop for a delivery, and the fact that you are to drive the truck your-self and will therefore be careful to avoid the unaccessary use of gasoline and oil may render the purchase of a gasoline truck a most profitable investment. We would suggest one of the thousand pound would suggest one or the thousand pound vehicles with a covered body. With such a truck, you could easily cover the dis-tance from your dairy to your nearest cus-tomer in less than half an hour, and the simmler of deliveries made in a viven time.

# **Electric Trucks Give** Long Service

RELIABILITY is the keynote of Electric Vehicle design and construction. Note these facts: There are several Electric Trucks of 1899 model still running. F. A. Poth & Sons Brewery, in Philadelpha, is using dailyan Electric Truck sould selectric bulls for B. Altman & Co., in 1896, is regularly used. All of these first users have incorrebought frequently. You really should investigate Electric Trucks now. using daily an Electric Truck delivered 11 years ago.

Several of the Electric Trucks operated by the New York Edison Company have been in use 10 years. An been in use 10 years. An Electric has been used by Frederick Loeser & Co., Brooklyn, for 11 years; another by Stern Brothers, of New York City, for 9 years. Three of the Electric Vehicle fleet of Tiffany & Co. were delivered early in 1901.

# What Is Old Age?

(Concluded from page 409.) the medium on the cells, was that the um may not only change the dynami possibilities of tissue, but that the char acter of the change may be regulated by a carefully considered modification of the

The question of the influence of the cells on the medium was taken up in turn although it has not, as yet, been studied

This involves the theory that the cells, in the course of their activity, make such demands upon the nutrition supplied by the medium as to deplete it; and that they e the indirect means of introducing into the life process, a chemically destructive agent (catabolism). The result is a gradual slowing down of cellth; in other words, progressive ageing of the tissues and death!

An analogous course was followed in early artificial cultivation. The tissues lived their normal span of life—i. e., a few days—and then died. But it was found that the process of degeneration could be obviated by the processor ageneration has been already spoken of as insuring "permanent life." In other words, death permanent me. In other words, death -for experimental purposes along these lines—has been overcome. These grow-ing in vitro for nearly a year and a half. now continue to multiply faster than those of the embryo. Time, for tissues under these circumstances, simply does not exist.

The burning question is; can this or anything approaching it, be done—ultimately-to solve the same question in the

# Labor-saving Appliances in Hotels (Concluded from page \$12.)

is a first cousin to same, without the bottom, of course. Knife-cleaning and allver-polishing machines, dough mixing and cutting machines, power-driven, are famil-iar. The dishwashing machine is perhaps the most extensively used power equip-ment on account of the large volume of the serving work which it handles; since of every order of food means dirty dishes. The dishwashing machine of whatever type operates by bringing the dishes into type operates by oringing the disnes into contact with a mass of hot water contain-ing a strong cleansing compound and after-wards rinsing them in clear hot water, and some machines add a finishing touch by sterilizing the dishes in live steam. A ical machine handles the dishes in baskets, swirling the hot cleansing water around and among them, the rinsing leav-ing them so clean and hot that they are dy for service without drying with a loth. The best results with any of the machines are obtained by team work, the helpers giving special attention to greasy and "eggy" dishes as they fill the baskets Although the work of machines compares favorably with that of ignorant and uncleanly hand workers, a deplorable short coming in the use of these machines is man; places is that the washing and rins ng waters are not changed often er A law has just been passed by the New York State Legislature and signed by Governor Sulzer prohibiting under penalty as a misdemeanor the use of dishe save not been previously cleansed in a sanitary manner, and prohibiting the n in such cleansing of water which has b come unsanitary by previous use.

Floor scrubbers and polishers, motor driven, are coming into use to replace the drudgery of human labor on cement and marble or mossate floors and on hardwood floors respectively. Vacuum cleaning is usually done two or three times a week. Laundry machinery includes large man-gles for "flat work," manned by a crew of six or eight men, a number of special de-vices for nursing collars, shirts and cuffs into shape in imitation of the best hand work, but with a far larger output than would be possible without a prohibitively large force of workers In one great New York hotel employing about 125 person in the laundry department, from 61,000 to 63,000 pieces of laundry are handled every

th, value of \$100 to \$300 a: day. By means of the ciaborate equipment of spe-cial devices employed—an expensive plant, warranted by the conditions obtaining in a hotel of enormous size—a guest can have his laundry done up and delivered within three hou

within three hours.

The saving of materials by mechanical devices is closely interlocked with the cleanilness and uniform good service also attained by their use. The handling of ice manufactured in the hotel's own refrige ating plant, is an example. The cold brin from the refrigerating machine serve rectly to "keep" the large tubs of ice cream, thus saving the crushing and hand-ling of ice for this purpose. The product of cake ice is cut into cubes by a ga machine and shaved by another machine respectively for serving iced water and chilled fruits, etc., at the tables. Drinking water for guests' rooms is howeve erved in vacuum bottles filled with the cooled drinking water from piping through out the hotel. This dispenses very satisfactorily with the formerly inevitable "ice water pitcher," with its clinking contents of dubious ice. A number of food dispensing appliances, primarily designed to give satisfaction to guests by serving a uniform quantity and quality, also prewhich would otherwise be considerable in the aggregate. One of these devices is a butter cutting machine consisting of a receptacle for the mass of butter with a plunger which extrudes the butter through a row of small gates each the size of the individual pat of butter the size of the individual pat or butter served to guests at the table. At the right moment a wire is pulled down, cutting off the whole row of pats. A simpler device eccomplishes the same result in a some what more pleasing manner: a hand im-plement for scraping off "butter balls" from the top of a tub of butter, a single quick movement rolling up a little scroll like a golden rosebud, into the hand of the worker. A cream dispensing recep-tucle delivers just enough cream for one cup of coffee or for a pot of same by a single turn of a faucet which closes automatically when the required amount has been delivered. This appliance saves a few seconds of time; but its principal value is in preventing waste by running over in the rush and hurry of the waiter's work. The French salad dressing dispens-er works on the same principle, but has the additional feature of a stirring devices which keeps the oil and vinegar well mixed in the receptacle so as to insure uniformity in the portions dispensed. Guest ordering fresh-made tea of some particu tion by a tea dispensing receptacle deliv ering an exact modicum of tea leaves by pulling down a lever A pancake batter dispenser for use at the griddle enables an inexperienced boy to produce paricakes of uniform size and thickness.

# The Current Supplement

IN this week's issue of the SCIENTIFIC AMERICAN SUPPLEMENT RAYMOND F. Nailler writes on the art of enameling steel and iron.—In an article entitled "The Modern Car and the Noise Problem," Lewis Kingsley tells us of "little refinements that make for silent running." The adjustment of local time in a large country like ours is a problem of some little difficulty. How it has been solved and how a compromise is struck between theoretical requirements and the exigen cies of practical conditions is expia liarian T. Steison in an article accom-panied by charts and illustrations.— Harold J. Shepstone tells us some interout the bat, the only man esting facts ab mal equipped by nature for flight.—The strategic position of Switzerland is altogether peculiar among European coun-tries, and the movements of the Swiss tries, and the movements of the Swiss army call for most remarkable perform-ances on the part of the soldiers. One of the articles in our current Suprissams describes a very wonderful fest, the march of a line th ree miles long of tors movet employing apout 125 persons march or a the turbe miles long of ropes of the third way of the control of the control

U. S. GUTTA PERCHA PAINT CO

No. 83 DUDLEY STREET

PROVIDENCE, R. L.

It has been said that a regiment is simply a multiplication of its Colonel. The same thing is true of any kind of management. To multiply himself—to duplicate his own efficiency in every unit of his force—that is the manager's ideal.

So that a manager who is looking for 100% of efficiency in his force must first find it in himself. And to be fair to his force he must first be fair to himself. He must give himself all the chances of generating the fullest man-power.

The head of a sales division in a big western Indiana plant got hold of this idea and applied it with what he at first thought was some success. But he found himself working harder than ever, and the strain began to tell.

It was then that one of the directors happened to introduce a visiting electrical engineer who spent several days in company with the sales chief. By this time the engineer felt free to talk plainly.

"Mr. Blank," he said. "You're a splendid example of energy, but you're not giving yourself a square deal. You're not giving yourself the right help."

"The right help!" cried the manager. "Haven't I got a fine force here?"

"Your people are all right, and you've made them imitate your energy, but neither they nor you have the right help. You're all working, so to speak, with old-fashioned tools. The help you all want is electricity. Yes, I know you've got electric lights — old-fashioned ones in the wrong places. But there are at least twenty ways in which electricity could help you that you're not using—

twenty more people would not help you so much and would only be an additional burden to you. Some day they're going to cut out all that overhead belting and shafting over there in the factory and use motor drive for each machine. Meanwhile you could apply that electric drive principle to the people in your office here. You could apply it to yourself. With the

help of electricity you could do the same thing for this office that cutting out the overhead belting and shafting will do for the factory — make the general conditions better for all, and the particular conditions better for each.

"Let me show you what I mean—and your own case is most important, because if you are alowed down your force is likely to reflect you. Take your lighting. You yourself have poor light. You go after people or send after them, when a button in your desk would do the thing better and save hours of your high-priced time every week. A moment ago you got up and opened your window. A little electrical help here would purify that air fuel your human engines are stoking up on. You're not using electricity for any of the mailing or adding machines—and that clerk who is mounting photographs, for instance, could do it in one-quarter of the time with an electric flatiron. I venture to say that you could accomplish 80% more work here with half the wear and tear if you made use of electricity in even a fraction of the ways in which it can be used."

This plain talk fitted in so well with the sales manager's first thought on the efficiency question that he promptly acted on the detailed advice secured from the engineer, and supplemented by the local electric light and power company. As a result, within a year he was able to compute that without increasing his office charges by a single dollar he was doing much more work and found himself in a position to shorten his own too heavy hours.

Perhaps you who read this have a manpower problem in your own person. Take up the

matter today with your electric power and light company or any General Electric Go. agent in your vicinity. You will find them more than glad to co-operate with you, and no matter how complex your problem may be they have at their command the service of any part of our organization that may be most helpful to them and to you.

# Pasadena's Beautiful Bridge

# Gracefulness of Line Achieved in a Work of Utility

THE huge concrete bridge at the head of Colorado Street, Pasadana, California, is the lougest and high-est bridge in the Southwest, and by all odds the most beautiful. The roadway is 100 feet above the channel of the Arroyo Seco, a stream flowing beneath the fines residential section of the city, and already highly improved. The nearly completed structure is quite in keeping with its beautiful surroundings, and the fact that it is built on a curve adds to its grace. The length is 1.468 feet, linking Colorado Avenue and a splendid boulevard by a roadway 28 feet between the curis. This will be paved with asphalt and flanked by two fivefoot sidewalks. No car tracks will cross this bridge, making it a perfect pleasure drive with wonderful views up the Arroyo to the mountains

The most striking feature of the bridge, saide from its long, sweeping curve, is the series of noble arches. the largest of which is 223 feet from center to center of ers, while there are two spans of 151 feet and six of 113 feet each. The arch spans consist of two con-tinuous, elastic arch ribs, carrying spandrel columns and in part spandrel walls. These support cross beams The massive piers rest upon the boulders and gravel of the stream bed and are tested to 11,000 pounds to the square foot.

Work has been in progress for more than a year, but a few weeks will see the completion of the important link in the California highway system. From 40 to 100

men have been constantly employed.

Cement to the extent of more than 10,000 barrels was required for the concrete, which is reinforced with corrugated bars of the strength of from 60,000 to 70,000

The cost will be \$300,000, balf of which is borne by Los Angeles County and half by the city of Pasadena. The designers of the bridge are Meesrs. Waddell & Haron of Kansas City.

rington of Kansas City.

As the photographs indicate, unusual skill has been used in designing a graceful as well as a utilitarian structure; in fact, it is one of the few of this sort that

# Flying in Fog and at Night By C. Dienstbach

By C. Diesestach

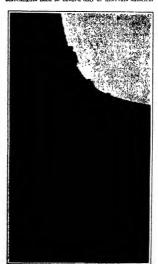

TivE years ago an sir pilot would sacend only
acture carefully studying the wind. A paffy bresse
would so far intimidate him take its would not venture
into the str. All that is changed now. Flying machaines teep from the ground in all weathers. Fog alone
seems a familicap.

The German Kaiser maneuvers of 1912 the greatest continuen was consulted by fog. Scouting both in
the str. Sand on them was completely paralysed. But,
stream assistant than the str. Sand on the str. Sand on the str.

Stream assistant than the str. Sand on the str. Sand

that is reasonably noiseless, there seems to be no renson why fog should prove a serious embarrassment Noiselessness can easily enough be attained with the aid of an efficient muffler. Whatever slight loss of er may be entailed by its use is compensated for by the ability to approach an enemy unobserved. Moreover, the muffler need be used only in the proximity of an enemy or when the crew wish to talk with each

Scouting in a fog very much resembles scouting at night, and night-flying is by no means unusuai Although a strong searchlight must be used to make nocturnal flying possible, the nocturnal scont should nevertheless be able to perform effective work. The searchlights need be theshed only at intervals sufficient

The beauty of the bridge ranks it as a work of art.

is numerous to guide the aviator. Thus used, it may even confuse and demoralize an enemy it certainly does not betray the location of the shifting air scout. So a muffler may be used intermittently with like effect

A flying machine that vanishes in stience and darkness and is heard or seen only at fifful moments can be safely used at night or in a fog. But the muchine must fly low. To fly low it must be very stable, because the wind is usually much disturbed near the ground. Many inventors are now engaged in making the aero-plane stable and safe, so that civilians will not be afraid to use it. The principal military significance of these promised improvements lies in the fact that they will make low flying possible. For war at least the will make low plug possible for war at least the unsafeness of the early aeroplane was not probliditive Soldiers expect to risk their lives, whether it be in the air or on the battlebeld that even the war aviator demands more of a machine than could be fulfilled by the aeroplane of 1908. Above all things he demands stability, not so much because stability means sufety us because it means the possibility of flying low

achine which is capable of skirting the ground and the aeroplane becomes hundreds of times more efficient than a body of cavalry--more efficient in the ability to find its way, more efficient in seeing things in detail, and more efficient in doing service at night and in fog.

Low-flying, however, means not merely stability, but also a reliable motor. Even now the risk of a break-down is less than the danger from bullets. There is no choice of a landing place in case of a breakdown. Hence, the motor must be dependable Some day we that the military aviator can desire

# To Our Subscribers

WE are at the close of another year—the sixty-uluth of the Scientific American's life. Since the subscription of many a subscriber expires, it will not be amiss to call attention to the fact that the sending of the paper will be discontinued if the subsending of the paper will be inscontinued if the sub-scription be not renewed. In order to avoid any in-terruption in the receipt of the paper, subscriptions should be renewed before the publication of the first basic of the new year.

To those who are not familiar with the SCHENTIFIC AMERICAN SUPPLEMENT a word may not be out of place. The SCIENTIFIC AMERICAN SUPPLEMENT contains articles too long for insertion in the SCIENTIFIC AMERICAN, as well as translations from foreign periodicals, the information contained in which would otherwise be inaccessible. By taking the Scientific American and SUFFLEMENT the subscriber receives the benefit of a reduction in the subscription price.

# Lifeboate on Lake Stummers.

SWEEPING legislation that fails to take note of local conditions and other modifying circumstances, is greatly to be deprecated; for it may frequently secure a trifling amount of theoretical good nt the cost of a large amount of disastrous harm. A case in point is a bill which is now before Congress. under which the passenger steamers on inland waters would be required to carry sufficient lifeboats to accommodate every one on board and two able seamen for each boat. It is contended by the Great Lukes shipping peo ple that, if this bill becomes law, the ships will be so lumbered up with lifeboats and so crowded with able seamen, that passenger-carrying capacity will be cut down to such a small figure us to render the ships sitogether unprofitable, and drive many of them entirely out of service.

As illustrating how this able seamen and lifeboat pro vision works out on one of the modern lake ships, we present the following facts: A lake massenger steamer, with a carrying capacity of 8,000 people, such, let us say, as the ship recently illustrated in these columns, carries a minimum crew of 180, all of which crew is regularly drilled in the intuiling of lifeboats, fire pro-tection apparatus, and so forth—life life-saving equipment consists of eighteen 30-person lifeboats, thirty-four 15-person liferafts, and 3,500 life preservers, besides other miscellaneous equipment. Under the pro-posed bill, for the same number of passengers, this ship would be required to carry 115 thirty-person lifeboats and an additional crew of over 200 men known as able seamen and these men would have nothing what ever to do except hundle the ours of a lifeboat in case of disaster. The extra men required could not be provided with quarters, except in the passenger department, and because of the great reduction in the pa ger carrying capacity, due to this invasion of the pas-senger quarters by the crew, and the great additional expense, it does not take the eye of a shipping man to that the chaire of such a vessel earning her dividends would be very remote

Now to one who is familiar with our columns will secuse the Scientifu American of wishing to call a section the present probleworthy efforts to make pas-senger slip travel as safe as the circumstances of the case will permit. We believe, however, that the best lifebout is the ship liself, which, by proper subdivision of her buil and precaution against fire, may be made so safe against any but the most extraordinary of dis-usters, that passenger travel by water shall not only compare favorably, but shall be superior in the matter of safety to any other means of transportation

However safe a ship may be rendered by subdivision and other well known means, it will be always necessary to energy a certain manism of lifeboats. But we believe that in this mutter good judgment should be used, and the number of boats in proportion to passengers carried should be regulated according to the condition which any particular steamship service is carried son No one would think for a moment of demanding that boots shall be provided on the Hudson River steamers in sufficient numbers to earry every passes wer on board.
The proximity of these steamers to the shore on either hand renders such precaution unnecessary Conditions in coast and lake service demand that the number of lifeboats should be increased; but even here we believe

that the question of lifeboat accommodation should have a distinct relation to the nearness of the coast lines to the steamer route. It should be determined, also, by the extent to which the hall of the ship is safe-grarefed against sinking by subdivision with builkheads.

# Goethals on the Panama Canal

E have before us the annual report of Col-George Goethals, Chairman and Chief Engi-neer of the Canal Communication No neer of the Canal Commission, which has recently been submitted to Secretary of War Gartison. It is significant that no definite date is set for the official opening; nor is there any precise prediction as to when ships will make their first passage from ocean to ocean. In the early days of canal construction it was thought that the building of the massive monoit was talegar that the binding of the massive mono-lithic looks would be the determining factor in the question of the time of opening; as indeed it might have been but for the development of slides in the Culebra

The regast states that the canal proper, if we exclude the approaches, machine shops, warehouses and the large occas docks at each end, would have been completed during the last fiscal year, had it not be plated during the last fiscal year, had it not been for the totally unexpected magnitude of the Culebra slides. As for these, no effective way was found to deal with them, except by bodily removal of genetically west hitte of material. Furthermore, the slides and be of material. Furthermone, the summe arms measure in the banks increased in seventty as the cut want down. It was found that the only effective way to deal with this stupendous problem was to excavate and haul away the material from the moving man, until the silder to rest, or until the angle of re-

('ol. Goethals draws attention to the fact that it was predicted last year by geologists that the sildes bad been conquered, and that because practically all the e surface soil and stone had slid off, exposing great ridges of solid basalt rock, this last material would act as a barrier to further earth movement. Nevertheless when all was most promising and the canal excavation within sixty feet of the bottom of the cut on the east side, the rocks broke under the enormous overhead east side. (her rocks bruke timeer the enormous overness up-pressure, and 2,000,000 cubic yards of material moved into the excavation and closed up the cut. The mass was attacked by giant dredges working on the face of the side; and powerful hydraulic monitors, similar to those extensively used in hydraulic mining on the Pacific Coast, were brought into play to wash away the hill from the rear and carry the material into uned valleys at a distance from the canal.

It is explained that water was admitted to Culebra

cut under the belief that the effect of the water in the cut would be to retard the slides, an expectation which was justified by experience obtained belo w the The geologists, on the other hand, the the water might to some extent develop new slides. Furthermore, in 1900, there was much speculation as to the effect of the seamy character of rock on the lsthmus, and it was predicted in some quarters that there might be a leakage of the Gatun Lake through nere might be a leakage or the Gatun Lake through seams and crevices. If those things are table to occur, says Col. Goethals, the sooner the better, if the official opening of the canal is to occur January 1st, 1915; for if the water had not been admitted this fall, but had been deferred until May 1st, 1914, the full height would not be reached until October, 1914, and this would leave little time for the delermination of these ques-tions. Hence it was decided to admit the water at the earliest possible date for getting the dredges into the cut and at work on the slides.

It is gratifying to learn from the report that the it is gratifying to earn from the report that the mechanism of the locks and dams has been tested with perfect success. The gates at Gatun were swung in one infinite and fifty-one seconds time for each. The massive feuder chains, whose dairy it will be to prevent a vessel which has got away from control from crashing lute the locks, were raised and lowered in plenty of time to meet any emergancy of this kind. They demonstrated that they could check or actually stop my vessel, unless she happened to be of very stop any vessel, timess she happened to be or very great size and navring at excessive speed. The electric towing icomordives which will handle the ships in the locks proved their ability to chally tow the largest ve-sels. A successful test has also been range of the electric installation

Up-to-clair Fereign Testimeny on American Telephone Service.—A member of the Pittish Partiament who has nades zone study of the telephone services in Cliffsong. Seattle, New York city, and Canada, stated recently that they were distinctly more efficient than the telephone service in his country; although not more efficient, be believed, than the latter would be. England was ahead of the United States in the development of the automatic exchanges of the total value of nearly half a million dollars were heing placed.

Bacquare' Microphone.—The microphone is now used by hurplars for picking combination looks. On turning the look a slight sound is made when the proper number somes apposite the working point, and this can even be heard by a sensitive sex. However, it is impreceptible to most persons, but by using a microphone it is an easy matter to hear the sounds. A suitable form of flat telephone receiver is employed, and it is applied against the asse next the look. A pair of rubber car tubes are used with the telephone. In this way the sounds are insert which allow of opening the look.

As advantage of Terbine-electric Marine Prepulsion.
—The steam turbine shows its highest efficiency at a high speed of rotation, whereas the marine propeller mast be driven at a rather low speed. The problem in efficient marine propulsion by the turbine is therefore how to combine a high speed curbine with a low speed propeller. Two methods of delivering the power of the turbine at reduced speed have been developed; reduction specing between turbine shaft and propeller shaft, and an electric generator driven by the turbine and supplying electric motors on the propeller shaft. An English contemporary points out that although the former solution has been the most widely skepted, it is at the disadvantage that the main power can not be reversed, and speeds turbines must be installed for maneuvering the ship, whereas by the electrical method the entire power delivered by the turbine can be reverted at the propellers.

the entire power delivered by the turbine can be reversed at the propellers.

Time Signals From Elffel Tower—It has now been definitely desided that the Effel Tower shall be used at the center for the world turned distribution solones. The members of the Time Conference shell at Para recently adopted the statutes of the International Association, and fifteen governments have about 1 thesis expected that other states will follow before long. The new association ag attented in Paris and the vireless signals will go out from the Tower twice a day at the determined hours, this corresponding to the Greenwich meridian as corrected by observations set level by astronomers the world over. The jouts all over the globe will receive the time signals said slight, the transmit teem within these own assays, so that in a very short space of himse the hour will be known within one-immdrath of a second. Pref. Bearik Mohn has retired from the professorably of meteorology at the University of Christiana and the directorably of the national meteorological service of Norway. He is succeeded by Akael S. Steen.

Prof. Mohn, who was born in 1830, has long been the dean of the International Meteorological Committee, and is one of the most distinguished and revered of European scientific men.

European setentifie men.

A New Pricial Amazeule Expedition is being organized by J. Foster Stackhouse, a well-known English traveler and geographer. The expedition is expected to all from England in the steam yellow it Polaris' in August, 1914, and to spend two years in an exploration of King Redward VII. Land, the region cast of the Ross Barrier discovered by Capt. Scott during his first journey to the Astantic.

The Ventilation of Motion Picture Theaters urgonity demands attention in most of our cities. In Chicago, which has about 600 of these institutions, with a daily attendance of about 500,000, the Department of Health has adopted the plan of issuing certificate to all theaters having ventilation systems of proved efficiency, and urging the public to patronize no theaters where these certificates are not displayed. Let us hope the next object of attack will be the hermosically scaled street-card.

A Balabow Sees Long After Stanet in described by M. Durand-Gréville, in L'Astronomic. It was seen by L. P. Mernod at Sainto-Croix, in the Swiss Alps. spanning a valley between two mountains to the castward, and from a sketch furnished by the observe appears to have been a secondary bow, as fragments of another bow (apparently not a "supernumerary") were seen inside it. A complete and brilliant are was first seen 25 minutes after the astronomical sunset (on September 10th), and portions of the bow were still visible half an hour later.

International Scientific Congresses.— Petermonn's Mutteilungen has published a symposium of opinions from
summont geographere concerning the advasability of making radical reforms in the character and organization
of the international geographical congresses, and many
of the remarks thus elibided probably apply to scientific
congresses and conventions generally. The writers are
nearly manimous in recommending that these meetings
should hereafter be smaller, loss completions, and more
strictly professional. Herecofore the professional gographere attending the congresses have beguinore or loss
lost in a crowd of irrelevant persons, such as diplomats,
pleasure travelers, local officials, and dilettant. One
of the greatest benefits such meetings should confervis., intimate social intercourse between serious students—
is largely nuilfied by the formal character and overgrown size of the usual banquets, recoptions, and the
like. The root of the evil seems to be the conventional
idea that international congresses should be carried
out on an elaborate and expensive scale; in order to rassthe secessary funds the organizing committee is obliged
to woull the semiberably as a much as pessible, and the
local control of the evil general conference of the proposition of the proposition favor of the meeting is diluted in a corresponding ratio.

The Psigrimage to Meeca is still a standing monact to the health of the world, in spite of the analtary precautions adopted by the various countries concerned, including the Ottoman Empire. The American consultance of the Constantinople Amore and the Constantinople Amore and the Constantinople Amore and the Constantinople amore and the collected by the Turkish Sanitary Administration concerning the number of pilgrims who teavied to Meeca are ports of the Red Sea during 1912. There were 88,90% of these, most of whom came by way of Jeddish, and of this number 44,671 had to be subjected to quarantine or other manizary measures. Stassistes of those arriving by the Hedgian Realway and other overland routes are not given, byte it is kepwer that the annual number of pilgrims often exceeds 160,000. In 1912, 198 vees-he were ongaged in earrying pilgrims, of which 134 were Sribtis, 22 Russian, 13-Dukth, and 29 Ottoman. # The Enlargement of Sculpture

The Pointing Machine With Which the Sculpture at the Panama-Pacific Exposition is Being Enlarged Under the Direction of the Inventor of the Apparatus

By Jay Hollingsworth

 $\mathbf{I}^{N}$  very early times the number of sculptural types was so limited that there was really no need for the sculptor to make n model in clay before beginning to carve a statue in stone or marble. Such variation as he might introduce into his work was rather in th study of detail than in the general conformation of the figure; and aithough he may often have made a sketch in clay of what he had observed in nature, there is no reason to suppose that he worked this into a full-street and complete clay model before he began cutting into the block of marble. When we come to the period of

artistic freedom the conditions are altered Then it seems most likely that the sculp-tor embodied his first conception of a work of art in clay or wax, but that he cut the marble more or less free hand.

The confidence and freedom given to an ancient sculptor by the force of tradition, hereditary skill, and training, as well as by the constant observation of the Hying and moving human form in the pale stra and elsewhere, gave blm a great ad over the modern artist who is mainly dependent on the study of posed Moreover it was easy to obtain the finest marble so that if a block or two were spoiled it did not so much matter. It seems likely that the Greek sculptors of the finest period of urt often worked freely in marble, and it is recorded that Michael Angelo often did so

In times when genlus and inspiration were less frequent, and art was more a matter of academic study we find that the use of finished models became as univer-

sal as it is at the present day -that the form of the full-sized model was transfer by the same mechanical process still in use, and that the method of enlargement was the same laborious method in common use until displaced about ten years ago by the time-saving pointing machine, devised so as to do its work with mathematical precision.

By whatever method, the copying of a model of a statue on a larger scale is done by measured points on the surface, hence it is cuiled "Pointing" by sculptors Points most salient and helpful to the eye in best trace ing the form are selected-the time, the seriousn

finish of the work in hand determining the number of tudate so measured. From time Immer orial this work whether in carving or in building up models in plastic materials for modeling, has been done with dividers und catipers of different shapes and sizes convenient for the measurements to be made. The process of measurpoints by this means requires m skill, and is at best only approximate.

First a series of points, a dozen or so in number, convenient for outlining the general form of the figure or group are selected as bases of measurement and

figure is to be twice the height of the model, each line connecting two surface points (sides of triangle) on the unitrad figure should be twice as long as that connecting the two corresponding points on the model. After the three points are determined, three measurements are required to locate the fourth as well as all remaining points. Further it is desirable that the fourth point be so taken that any two of the three lines con-necting it with master points should be at about right angles. With this in view the skillful pointer so places master points that any point on the surface of

figure or group can be commanded by measurements from three master points measurements from three master points— lines to which make three approximately right angles. Of course to measure all points is impossible, but enough are taken to give a general outline of the surface of the enlarged figure.

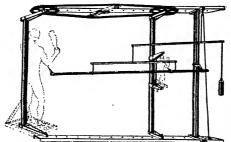

To render measurements from the model into measurements on the enlarged figure, sculptors use a "scale" made in one or another of several ways, all of which em-ploy the principle of similar triangles. one most commonly in use before the whole method was displaced by the po ing machine was a right angled triangle in which the hypothenuse was the height H of the cularged figure, and one side h the height of the model. Measurements on the model will then be taken on lines parallel to h, and the corresponding hypo-thenuse of the smaller triangle will be the desired measurement on the enlarger It is said that a brass plate presumably

a "scale" is still to be found on the base of the Egyptian Sphinx on which are drawn similar triangles. This would indicate that the method of culargement, until so recently in use, is as old as the most socient sculpture. But the marvel is that so laborious a method and one admitting of so much error could have persisted so late in this age of

a movable shaft one end of which is always on a fixed point (at the right in the drawing). Attached to this shaft are two movable arms each ending in a sharp

scientific method.

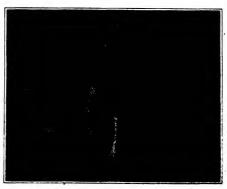

cluded on page 444.)

marked on the plaster model each by a tiny nail with a fine dent pricked in the head for receiving the point of the dividers. Minutest care must be exercised in placing these "master points" and in finding their corrending points in the enlarged figure, as the exactness of all the measurements depends upon their accuracy. The first point on the enlarged figure is placed arbitrarily, the second by one measurement, the third by two measurements. These three points determine a tri-angle similar to the one whose vertices were the three master points on the model. That is, if the enlarged

Becently opened mine of soft asphaltum at Carpenteria, California, showing a part of the deposit stripped of soil, and the depth both of soil and deposit.

THE sephsitum deposits of California are confined to a narrow strip of territory near the coast and extend, broadly speaking, from Ban Francisco on the north to Los Angeles on the south. They consist either of andstone impregnated with bitumen, or of asphatic oil mixed with sand. In common parlance, the former taked spatialism, the latter soft, a condition due in the one instance to loss of volatiles and to their retention in the other. By far the greater part of California

amphatium, aside from her extensive fields of asphalite oil, is in the form of bituminous rock and the percentage of pure asphalitum is remarkably uniform, averaging from fifteen to twenty per cent. Geologically, they belong with one exception to the Miccene epoch. In all this five-hundred-nile extent containing large areas of bituminous deposite hardly more than half a dosen districts have been opened up for mining on a commercial scale and the product has been utilised almost entirely for local needs.

The district where the greater part of the mining has been done are Santa Cruz, about fifty miles south of San Francisco: San Luis Obispo, two hundred miles further south; and several different sections of Santa Barbara County, a hundred miles on down the coast. Ventura and Los Angeles counties contain large Belds

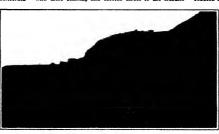

large area in Kern County, but asphaltum in the common acceptance of the term does not occur here to any large extent and very little mining has been attempted.

arge extent and very fittle mining has been accupied.

The Santa Crus deposit, situated eight miles west of
the city of Santa Crus, corers an area of five or six
square miles and was opened up thirty-five or forty
years ago. It occurs in a marked beit about fifty feet
thick at an altitude of eight or nine hundred feet near

MADE BANKER TO BE CONTROLLED

the top of Empire Ridge. This outcropping is covered by from fifty to one hundred feet of distonanceous shale, and it is of a dull gray color, the result of fading through long exposure to the elements. The freshly broken product is glossy black or brown. The mining process consists, first, in stripping it, that is, in removing the shaly covering. This is done with dynamates and scrapers. Then the suphairum is loosened with more blasting and carried direct to the steamer

View showing the working face of bituminous rock deposit, Santa Crus

landing, whence it is shipped to San Francisco and adjacent cities to be converted into pavement. The annual output varies from thirty to sixty thousand tons

annual output varies from thirty to saxy mousant tons.

The next section, San Luis Obispo County, contains an immense deposit of asphilium estimated at eighty aquate miles of surface with varying depths, reaching a maximum of two hundred feet south of Arroyo Grande. While it is smoog the best sprearing biru-

minous rock in California, the deposit has been very little develored. Twenty or more openings have been made, but most of them have been idle for a long time. One that has been actively worked, known as Weng Quarry, southwest of the city of San Luis Oblepo, is located near the top of a mountain ridge, and like the Santa Cruz product, it is hand and is mired at the face of the cilff by blasting as before described. It is then reduced by cooking in burge doubte boller arrangements,

or else steamed until it attains a mealy consistency that can be spread for paving purposes.

purposes.

Santa Barbaru County contains numerous deposits, some of which have been uncovered while others have been uncouched;
probably many are undiscovered. One
that was worked for a time and then
nhandoned, is a few miles from Casmalla
and contains a very rich as well as uneven percentage of pure asphatium, ranging from twenty-nine to staty-sight percent in the same deposit. Another is near
Los Alamos, in the central part of the
county, where there are three nearly
parallel mountain ridges, the middle one
of which is the location of what was about
fifteen years ago one of the most axienvive and interceting asphatium mines, not
only in California, but in the world. It
was known as the Slaquee mine, named
from a creak near by. This, like the doc-

posts aiready described, is near the top of the ridge, and the suphistum is hard and was obtained by the usual arripping and blasting processes. The extent or the deposit has never been determined, but it is known to be a big one. A large amount of machinery was ministalled at great exposes for developing this mina, for besides cable curs to carry the product the short distance to the reducery it was necessary to devide order to state to the reducery it was necessary to devide some

They shoulding deposit of hituminess spet man fine Luis Oblopo, California.

View of complete working face of bituminous rock deposit, Santa Cruz, California.

means of preparing it to be transmitted to the nearest shipping point. The scheme evolved was to extract the pure asphaltum by distillstion and then to mix it thoroughly with naphtha and pipe it by a gravity line to the nearest steamer lauding thirty miles away. Here the naphthu was recovered and pumped back to the mine for use again. The enormous expense of installing and maintaining the plant proved prohibitive and the alue closed in a few years

Au interesting feature of these mines is the pre

in the bituminous rock of large quantities of fossil shells, both gasteropods and bivalves.

Along the beach both east and west of Santa Barburn, there are bold outeroppings of asphaltum, and of this region the United States Geologic Survey report of "it cannot but be regarded nent in the oll-bearing nature of its rocks and the structure which has permitted its liberation." Of the two west of the city, one at More's Landing lies in a great cliff above the beach and has been worked but little while another at La Patera, near by, was at one th an important mine. Several fissures here extending slong the shore about an eighth of a mile are filled with asphaltum and have been opened to a depth of perhaps two or three bundred feet. This, too, is hard and brittle like the other deposits, and yet it has a tendency to cose up from the floor of the shafts, espe-cially below the hundred-foot level. It has been estimated that the amount of seconge collected in one of the shafts in a year's time was equivalent to a mass of asphaltum twenty feet in depth and of the length and width of the shaft. This tendency has made it impo-sible to penetrate to any depth in any of the veins because of the inevitable destruction of the timbering. This was among the earliest mines developed in the county and idek and shovel were the principal

About the same time that the mines of La Paters ed, another deposit of a different charac

was opened up at Curpenterla, twelve miles east of Santa Barbara. This was a low bed of soft asphaltum severa square acres in extent, alongside of the beach beneath a few feet of sandy soil.

A huge pipe line was laid into the surf order to strip the deposit by hydraulic means, a process that proved much more expensive than the other method. The asphaltum was then mined by means of hot shovels, the men working in an amphitheater of tiers of steps, cutting down each tier in sucsion and at the same time creating new ones. The shovels were heated by means of portable furnaces and cable cars carried the blocks of asphaltum to the reducery, close at hand, where the sand and volatiles were removed preparatory to shipping. After the varivats and stills had done their work the rich black pitch was poured boiling hot from great swinging caldrons into barrels that carried it to all parts of the country. The mine was worked the most of the decade from 1890 to

1900, and then a large part of the machinery was transferred to the Sisquoc in the belief that the new venture would pay better. Ever since then the Carpenterla mine has lain idle.

A year ago, however, another extensive soft deposit A year ago, nowever, another extensive sor, deposit, half a mile distant, and uncharted by the Geological Survey, was prospected with the result that it has proved the most perfect road making asphaltum yet uncovered. It was once an oil lake that became entirely absorbed by sand that drifted in in almost the precis percentage of course and fine material required. It runs something over twenty per cent pure asphaltum, so that approximately only ten per cent of mineral ag-gregate needs to be added for road making. The average daily output varies slightly with the temperature use duly output varies slightly with the temperature of the air, as a warm day very perceptibly softens the aircady soft deposit and the viscous mass can be cut much more easily. At Trindad, on the other band, the men are required to work at night while the materiol is brittle

ai is brittle.

Besides natural asphaltum, California produces a nescioes naturni asponitum, Chitorina produces a large amount of the refined product. A large refinery for this purpose is located at Point Richmond on San Francisco Bay, and the oil is piped from Kern County, two hundred and fifty miles distant.

Three still more extensive plants are located in San Lais Obispo County, where local oll is utilized, and oll from wells as far distant as one hundred and fifty Heat is introduced through steam coils heat to from two to seven hundred degrees, depending upon the percentage of volatiles to be retained. In propor-tion as these are driven off the product loses its clasticity, hence the refined asphaltum is lacking in some of the qualities necessary to a good pavement. The life of the refined product is from five to seven years as

against fifteen to twenty years for the natural produ A place of natural asphalt payement laid in Santa Bar bara over twonty-five years ago, where traffic has been constant, is still in excellent condition, and it has received hut little repairing during this period.

One reason that there is no greater activity in Cali-

fornia asphaltum mines is the great cost of transporta-tion, with the result that Trinidad continues to compete successfully with us in the eastern markets. Her importation to the United States in 1911 was nearly 112,000 tens, and of our total domestic production the same year, 350,000 tons, California contributed a good same year, source took, cancerna contributed a good margin over half. The principal reasons, however, that so little mining is being done in these fields is the ex-pense connected with it, and the very limited demand for the asphaltum. When readmakers become more familiar with the durability of natural asphalt pavements and when the good roads movement gains greater momentum, it may be expected that California deposits will enter upon a new era of development.

# Automatic Wireless Train Control

By F. C. Coleman

CONSIDERABLE interest is being taken in an in-stallation of wireless automatic train control which has been laid down on the Hampton Court branch of nas been laid down on the manpion Court braisen or the London and South Western Railway Company. This system is somewhat similar to that which has been working for some time on four sections of the down line and four sections of the up line of the Canadian

Pacific Railway, near Toronto.

Under this automatic system of wireless train control invented and patented by Mr. Frank W. Prentice, a current of high frequency is sent along the line by means of a wire laid in the four-foot troughing on epers. This wire is known as the wave wire and it acts on an arrangement of antenna-technically known as the harp-which is on the locomotive, and is

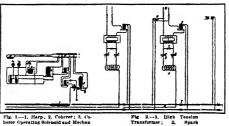

Fig. 1.—1. Harp, 2. Coherer; 3. Coherer (pprating Solesold and Mechaniam, 4. Detector Helbr; 5. Time Eiment Relay; 6. Master Relay; 7. Whitatie or Busser Nolesold; 8. Brake Valve Solesold, 9. Hold Reig; 10. Push Button; 11, Has Hare; 12. Sturage Battery, R. Red Light, 6, Green Light;

Track Transformer, 7. In-sulated Ball Joints; 8, Wave Wire; 9, One Hun-dred and Ten Volt, Sixty Cycle Feed Wires. Diagram of connections of the automatic wireless train control

Transformer; 2, Spars Gsp; 3, Condensor; 4, Heltz, 5, Track Briay; 6, Track Transformer, 7, In-minted Ball Joints; 8,

composed of nine wires. So long as the harp is receiving energy from the wave wire, a green visual signal is given in the cab of the locomotive. The high frency current enters an apparatus box at the end of the section, and its primary is controlled by a relay one section, and its primary is controlled by a reary connected to an ordinary track circuit. This relay, in accordance with the principles of track circuiting, now so well known, is de-energized when a train or part of a train is in the sectiou, and this causes the flow of the high frequency current to cease. The harp now no longer receives its energy, so that a relay on the loco motive is closed, and this causes the green visual signal to be switched out and a red light switched in. The brake is automatically applied simultaneously, and a

nrake is automatically applied simultaneously, and a whistle or buxer may also be sounderformer for the track circuits and one for the high frequency current, a spark gap, condensor and helix, also the relay, stready referred to, connected with the track circuit. Ou the otive, besides the harp, there is a coherer which is continuously recked—about eighty times per min-ute—by a solenoid and co-operating latch device. Work-ing in synchronism with the coherer is a relay controiled by a time relay, which in turn controls a mast relay. The time relay is provided to allow for decohence The last-named controls in its turn the solenoids used for operating the whistle and brake valves and ence the red light. A push button is provided to allow the driver to release the brake should the train be pulled up at an unsuitable place, but this does not switch out the red light.

The diagram of connections illustrated herewith setforth in greater detail the main features of the syste which has been outlined above. Fig. 1 covers the non ratus on the engine, while Fig. 2 includes the co-operat

ing arrangement of the track. The latter may present first attention. The track density is self-from agreement able source of supply 8—in this case 10½ with the track alternating current—through the transferance 6. The secondary is connected to the runting rathe, which are divided into the signaling sections, as essail, by feed intel joint at 7. The track circuit of one section pleases lated joints at 7. The track circuit of one section passes intrough the relay to fit he section behind, so that the presence of a train or vehicle causes short circuiting, thereby releasing the relay 5 for the section in, which the 'danger' intinaction is to be given. The high frequency plant, the primary of which is controlled by the relay 5, includes the transformer 1, spate; gap 2, condenser 3, and helix 4, and is of any satisfable character as long as it supplies the required high frequency current to the wave wire 8. It will, therefore, he seem that the wave wire 8. It will, therefore, he seem that the wave wire 8 continues to raceive high fr current unless the de-energising of the generaling track circuit relay by short-circuiting causes its cossition. On the engine, the harp 1, Fig. 1, transmits radiant

energy received from the wave wire to the coherer 2. This is, as has been explained, continuously rocked by means of solended 3 and its co-operating lated device. Relay 4 operated in synchronism with the coherer 2. being closed as the waves from the harp break down the resistance of the coherer and reopened as the resist-ance is re-establishd. Its closing completes the circuit ance is re-establish. Its closing computes the execut of relay 5, but as the latter is of a clowly de-energising time design, it holds over the pulsating action of the relay 4, causing continuous action of the master relay 6 as long as the influence of the high frequency waves on song as the moment of the sign requestry waves from the wave wire are felt. The meater relay 6 con-trols solenoids 7 and 8, respectively, which are used for operating the whitch and brake valves, and also the display of the red or green light. The latter is continuously presented, while the high frequency waves are being received, but immediately the influences is lost, the green changes to got the brakes are amounted and are being received, but immediately the influence is lost, the green changes to red, the brakes are applied, and a whistle or buzzer is caused to sound. The holding relay 9 for the brake system is fitted

with a push button 10, whereby the driver can release the brakes to con-trol the running of the train at discretion through the remainder of the sec-tion; but the red indication continues to be displayed, and the whistle or buzzer to sound so that the driver cannot possibly ignore the warning he has

If the section shead becomes clear whether the train is standing or is still moving, the corresponding track circuit relay is again actuated, re-establishing the high frequency circuit, and thereby restoring the indicator, brake and whistle or buszer relays to "line clear" conditions. It is pointed out, the that (1) the driver receives a persistent "danger" indication, in combination with initial brake application; (2) subsequent action at discretion is only permitted in conjunction with insis warning; (3) he is informed of the restoration of "line clear" conditions; (4) the apparatus involves the positive

maintenance of a "line clear" indication, in combina-tion with positive action in the event of "danger," failure or other adverse conditions. The automatic character of the installation is also emphasized by the inventor, who urges that it enables a line to be worked ventor, who urges that it enables a use to be worker to its full traffic capacity, there being no loss of time during the transmission of bell signals and the mechani-cal operation of a number of levers. It is claimed, also, cal operation of a number of levers. It is cistumed, also, that in case of fog a driver is given all necessary information as to the conditions sheed, even if he cannot see any of the fixed signals; that in circumstances where it is difficult to give a good look shead, owing to the layout of the line, the same advantages are resized; and that the installation mosts all requirements as regards asfeguards against the non-observance of signals. combining, ip., fact, the development, of the track circuit, now so strongly recommended in many quarters, with the direct signaling and control of trains. quarters, with the direct signaling and control of trains It has been shown in regular working that the effect of another engine on the section was sufficient to me of another engine on the section was sufficient to pull up a train against full steam, and with the regulator

# mburg University Extended for Science

THE new university at Hamburg is an extension of the important colonial institution known as Kolon-It the important colonisi, institution known as Kolon-inilizatitut which was founded in that city at a previous date. The university is to have chairs of philosophy, law and colonial sciences, and the annuar bodges will be 2590,000 marks. Upward of 15,000,800 marks will be expended for the construction of the respons institu-lings, comprising the different institution amount in the university. One of the interesting features is the uni-versity extension scheme which provides public and from evening courses.

# To Strike the Pentagram

To the Editor of the Scientific American:

The method of striking the pentagram or pentacle, prepased by Mr. John P. Robinson in your issue of prepared by Mr. John F. Monison is your issue of Keewither 22nd, is legatious, but less accurate than the old-fashioned way of dividing the circle. This will appear to anyone who will carefully measure the draw-ing shows, or will attempt to construct the figure from

ling shows, or wait statempt, to consists of any of the directions given.

In your drawing the lines 1—2, 1—5 and 2—6 are of equal length, but the lines 4—5 and 4—6 are longer than the others (and of course the spacing of the points is unequal), and this will be the invariable result of following Mr. Robinson's plan. This would not be a very serious matter in laying out stars for lawn coration and similar purposes, but nnless the primary es are exactly perpendicular to each other, the irregu larities above mentioned will be increased. More there are better ways.

he draughtsman has his own system of producing the pe entacle, but for the man whose needs are le exact, the following plan will yield a very close approxiexact, the following plan will yield a very close approxi-mation. Strike a circle whose diameter is eighty, or some multiple or divisor of it. If the dividers are now set to forty-seven eightieths of the diameter they will almost exactly divide the circumference law five parts, and the points, when properly connected, will form the star.

This is sufficiently accurate for any ordinary work, and may easily be performed in the fol lowing man To divide a circle of, say, 20 feet in diameter, take a light strip of wood 12 feet long, and having fixed a center-pin at one end, drive a long nail 10 feet from it, and with this strike the circumference. Now one eightieth of 20 feet is one quarter of one foot, or 3 inches, and forty-seven eightieths are, of course, 11 feet and 9 inches. Remove the nail, therefore, and drive it that distance from the center-pin, and placing the latter at some point on the circle, scratch across it with the nail. Place the pin at this point and repeat the operation, and so on. If carefully done, it will be found that the variation is a negligible quantity. Small nine may be driven in the proper places, and a chalk-line stretched from one to another will produce the figure desired, without resorting to the "cut-and-try" method formerly in vorue.

uppose, as another example, a farmer wishes to cut a star-shaped ventilator in the gable of his barn. Let him strike a circle of (say) 10 inches in diameter. Ten inches contain eighty eighths, and by setting his com passes to forty-seven eighths (5% inches) he can re-ily divide the circle into five equal parts.

In using this method it is better, when practicable, to take one of the ordinary divisions of the carpenters' rule (sixteenths, eighths, quarters, halves, or inches) as the unit of measurement, and eighty times this unit for the diameter of the circle, as it facilitates finding the fraction (forty-seven eightieths) necessary. This plan has no advantage over the older one of pricking off the circle, except that it is more expeditious. It is only necessary to remember that forty-seven eightieths of the diameter of any circle is almost exactly seventytwo degrees of that circle, and this fraction will serve for laying off pentagons or pentacles when-lute accuracy is not required.

# A Suggestion for Government Automobile Road

To the Editor of the SCHNTIFIC AMERICAN:

As the question of Government road building is like, to be discussed in Congress this winter it might be

a good idea for opinions to be given as to what kind of roads the Government should build or assist to build. I think the Government's chief interest in road building is in the more important roads which should run ing is in the more important roads which should run from the principal seaport cities to the principal inter-lor cities. The first road to be built should start from New York and should be surveyed near the Hudson of River, the Rite Canal, the Lake Erte shore, then on to Chicago, and from there on to New Orleans see St. Louis. Such a road should have no grade crossings Louis. such a read should have no grade crossings and should have a surface width by not less than 100 feet, the central portion should have a finished surface at least 25 feet wide built as well as the best city street, the 'remaining width on each side should be dragged the remaining width on each side should be drugged and kept as uncot as possible and rested with oil or office preparations which experience might prove to be best fer impriving each roads. The object in having wilds roads would be to give plenty of room to avoid accidents. As a further precention there should be no loading or unloading of freight or passengers on the

Beile Brans & O. H. 1997

right of way. This should be done on the outside on ground provided by the cities for this purpose. Also the wide road would encourage the building of

wider automobiles with more wheels under them which would increase their carrying capacity.

The method of building such roads would be for the Gevernment to let the contracts for the grading; cul-vert building, fencing, and finishing the road, to coryear tending, teneng, and mining her road, to cor-portions. After the completion and acceptance of the work the Government should charge a toll to users of the road sufficient to pay for maintenance and a low rate of interest on the investment. In this way the nent would borrow the money to huild the road and then collect the interest and cost of maintenance from the traffic, which is precisely the way it proposes to do with the Panama Canai, a method which is fair eyond all question

This system of Government roads might be regarded as complete when a sufficient number of roads were built to take care of the interstate commerce. It might erce. It might be proper for the Government to contribute a small sum per mile for dragging the roads on the rural routes, but further than this I can see no justification for Gov-Ment uld

I wrote a letter to the Scientific American which was published in the November 30th, 1912, issue on the subject of "Antomobile Toli Roads" such roads to built and owned by corporations, allowing automobiles to use the road by paying tolls. Such roads would be excellent feeders for the Government toll roads, or the States could build their own antomobile toll roads just the same as the United States Government could, as explained above. A system of Government toll roads such as I have suggested I think should be used exclusively for automobiles, because the Government would re particularly interested in interstate commerce and interstate commerce is only possible on public roads when the automobile is used. Such a system of Government roads would also be valuable for rapid maneuvering of Proops in case of war.

Stanberry, Miss. Clifton R. Summers.

# Automatic Pilot for Signal Observation

To the Editor of the SCIENTIFIC AMERICAN:

Much is written these days about railway accidents their prevalence and their prevention tions of various character have been made and experi-ments have been carried out, yet the appailing death rate is not materially decreasing

According to some writers, the ideal prevention of accident would be to take the flual coutrol out of human hands and to make same entirely mechanical But the automatic stop will never reach such perfection that it cannot be tampered with, or that it can become abso lutely dependable in all emergencies. What manner of automatic stop could have prevented the collision with the huge boulder on the irack of the Chicago, Burlington and Quincy near Genoa, Wis., on the morning of November 3rd, when the train was wrecked and six men were severely injured?

e remedy lies not in perfecting automatic co but in making the human factor more efficient. Iu line with this thought I would make the following sugges-

On top of every railway locomotive, immediately be-hind the headlight, there should be constructed a small windowed cable or observation room, containing a cor seat for one person, whom we may call th pilot. Upon approaching or passing a signal the pilot would be required to touch a button or series of buttons which would register the fact that the signal had observed. The engineer would have a similar set of buttons to register the same signals. As the two observers could not communicate with each other to compare notes, there would be no dependence upon one another, and the reading of the recording instruments cials would be a check on th e watchfulness of both the pitet and the engineer. Further than thus recording signals, the engineer's duties would be in no manner changed from the present duties of an engineer. The pilot's cahin should also contain levers for emerg-ency control, so that should the engineer fail to observe a signal or to notice an obstruction, the pilot would be to bring the train to a stop.

An accident through negligence in observing algoris An accurate trough negigence in observing against would become practically impossible, as there would be two observers instead of one, and both would be more cureful than the engineer of the present, because the observations of one would be a check on the observations of the other, and neither would dare to let a signal unnoticed, through fear of the penalty.

plate unnoticed, through fear of the penalty.

The expense of multiabling such a system may seem exceeders, but this cost would probably be offset by the saving in rolling stock and lawanits, and the saving of the public demands that the railroads work for safety even though it should make extra expense.

The objection may be raised that the public's position so near the front end of the locomotive would be very perious in ease of accident, and that no one would want the job, Under the new conditions thus created the

pilot's position would be safer than the engineer's is at present; and, furthermore, a study of the matter may point out some better plan for attaining greater safety in this respect.

# Weather Prophets

To the Editor of the Scientific AMERICAN:

For many years I have been almost a constant reader of your valuable journal, and its timely articles are very much esteemed by a host of others besides myself As 1 am after sowing, planting and reaping, your article on weather forecasting, under date of November 1st, 1913, naturally struck my eye

What I did hope to find was a reliable forecast for say the next sla mouths; but you only hint at the schemes of the charlatan, the delusion of the crank and vaguely to some method in the madness of the honest ignoranous which enables him to find a incrntive market for his prognostications, etc

Whether you had in mind the Hackensnek weather prophet does not appear; but I saw it stated some years ago, on good authority, that Mr. DeVoe did not only sell his predictions to the farmers of the United States, especially those located in the West, but that he also supplied residents of foreign countries with his prog-nostications, presumably for a good price, if memory serves me right.

The old saw, "Give the Devil his due," may be appropriate, and as an honest, hard-working, natural-born citizen of the United States, I heartly indorse holding up to the limelight the mischievous doings of frauds. charlatans, ignoramuses, or canaks

Had you more definitely pointed out the activities

of such persons, by in some manner illustrating or demonstrating the schemes of frauds and charlatans, you would have done the general public-your patrons—a service, a favor; else how shall they be forewarned against parting with their money for what is worse -absolutely useless?

I, for one, should like to be thus posted and would appreciate very much another urticle on the same subject warning me in no uncertain way as to the scheme of frauds and unreliable persons who would fool the public, and especially the farmers E. Kozez Asheville, N. C.

# What Dr. Lardner Said About Steamships

To the Editor of the SCHNTIFIC AMERICAN In your editorial of November 15th, "The Future of

the Dirigible," you speak of the commonly accepted story that Dr. Dlonyslus Lardner proved mathematically In a paper before the British Association that it would sible for a steamship to carry enough cont to propel her across the Atlantic Ocean

As at that time stemmships had already crossed the occurs, I was interested and looked the matter up, and had the good fortune to find Dr. Lardner's original It proved, as I anticipated, that he never made paper the statements popularly attributed to him. What he really said was that in the state of steam engineering at that time it would not be commercially profitable to run n line of freight steamers between Li lverpool und New York, which was perfectly true—lie not only recognized the possibility of such a line, but suggested their use in the curringe of passengers and express

Since his day the invention of the surface condenser, the compound engine, the high pressure marine boller, and many other improvements, have revolutionized commerce and driven suiling vessels from many trade routes, except for the carriage of very heavy and balky freight, like coal, inmber, etc. It is only fair to Dr. Lardner's well deserved reputation that this error should be corrected, especially us the story is often used In connection with the exploitation of Keety motors and other scientific swindles, as an illustration of the un-reliability of scientific loyestigators, and the worthless Haverhill, Mass

International Safety-at-Sea Conference.-The Inter national Conference on Safety at Soa, which was formally opened on November 12th, is now in session at the British Foreign Offlee, London. In a message of welcome King George, who once commanded a British cruiser, says in part. "The question the delegates are about to consider is one in which I take a special interest, for it affects closely the lives and welfare of a vast number of my subjects; and as a sailor I have had personal experience in many of the matters which will come up for consideration by the Conference." The gathering is presided over by Lord Mersey who, it will be remembered, was the president of the British com-mission which investigated the "Titsuic" disaster. The twelve nations represented are the United States Great Britain, Belgium, France, the Netherlands, Russia, Denmark, Germany, Norway, Spain, Canada and New Zealand.

# The Origin and Evolution of Man

# Recent Views Suggested by the Discovery of the Piltdown Skull

By Dr. J. Leon Williams, Fellow of the Anthropological Institute of Great Britain and Ireland

If very widespread publicity on the part of the press is a fairly accurate measure of general interest in a ct, then the prominence and space accord recent interviews with me on the theme of prehistoric man indicate something more than mere curlosity on the part of the public. It has also been very interestto me to of erve that nearly all of the different parts of the country that have mentioned the subject have given special prominence to the statement of the great age of man on the earth. That is really one of the vital aspects of the whole problem of man's ecent discoveries have made it quite plain that the human race has been in existence for a much longer the numan race has been in existence for a much longer time than has generally been supposed by the major-ity of scientific men. The only alternative view that can now be taken is that evolution has not proceeded altogether along the lines of the Darwinian hypo-

Editors of the Scientific American, to deal with cer-tain phases of the subject which bear directly on this great problem. The main features of the Darwinian theory of evolution are too well known to the readers of this paper to require elaboration. They can be largely summed up in the two terms—variation and satural selection. The causes of variation are still obsoure; but the working of natural selection is patent enough to any observant and thinking person. nature of the environment exercises a profound modi fying effect on species, and it is highly probable that this factor in evolution played a much more important this factor in evolution payed a much more important part in the past than in the present. But all of these factors of the Darwinian theory work in a very slow way. Dr Alfred Russel Wallace told me, in an interw I had with him last July, that he did not believe a single new species had come into existence during whole Pleistocene era, and this, according to Penck, the great German geologist, covers a minimum period of 500,000 years and may possibly extend to 1,5

Accepting even the lowest estimate, one of two things is evident: either the conditions for the production of new species are much more unfavorable in recent than in early geological times, or Darwin was right in his earlier views that enormous periods of time were required for the production of species. But there is now in the field another school of evolutionists, led by the eminent totanist, lingo de Vries, who believe that species may appear quite suddenly. This has certainly species may appear quite suddenly been fully demonstrated in the vegetable kingdom, but peen runy aemonstrated in the vegetable kington, but Wallace regarded these as fresk or, at least, exceptional productions, which in no way militated against the fundamental principles of barwin's teachings. I will try to present very briefly, some of the evi-

dence now in our possession bearing on these two theories as applied to the origin and evolution of man. Prof. Arthur Keith, Hunterian Lecturer on Anatomy at the Royal College of Surgeons in London and anthor of "Ancient Types of Man," says, in describing a preor "Americal Types or Main, 8308, in describing a pre-bistoric skull found thirty feet below the surface when the great Tilbury docks were evenyated in 1888, and estimated to be between fifteen and thirty thousand years old, "In Owen's time those scientiats who had come, under Darwin's influence to believe to the evolution of man, expected to find to an individu ancient as the Tilbury man some distinct trace of his similar origin." But this skull was purely modern to type with no ape-like characters in evidence years later, across the river from Tilbury, the now years after, across the tree those kindless, the so-celebrated Galley Hill skull was unearthed in a high terrace of the ancient Thames. Prof. Keith asks for about 200,000 years<sub>spe</sub>as the age of this skull. Here again we have a specimen which although a little more

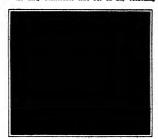

"find." is still essentially modern.

if, therefore, we find the modern type of man in existence 200,000 years ago, it becomes perfectly evident that we shall have to get very far back in the past to find that human relative of the anthropoids from which we have undoubtedly descended.

Let us for the moment leave these ancient records

Let us for the m of modern man and turn our attention to another and distinct group of discover

in 1891 Dr. Eugene Dubois, Professor of Geology in the University of Amsterdam, found on the banks of the Bengawan, at Trinil, Java, the top of the skuli, two molar teeth and the thigh bone of a creature presenting characteristics which placed him in a position about midway between the highest ares and the lowest human beings heretofore known. The estimated size of the brain was 900 cubic centimeters, that of the largest gorilla being 600 cubic centimeters, while the lowe Australian savages have a skuli capacity of about 1,200 cmbic centimeters. These facts and others of like nature led Dr. Dubois to give the name of Pitheomthropus creetus, or ape-man, to his Java discovery. There is still a difference of opinion as to whether these fossil remains should be ascribed to the late Pliocene or the early Pleistocene era; but on any reckoning

Dr. Woodward's restoration of the Pilt-down skull.

Fig. 5. Restoration of the Piltdown skull cording to Dr. Williams.

they are probably the oldest and most primitive hus relics discovered up to date. On the basis of Penck's measurement of geological time they are more than 500,000 years old.

In a rocky ravine, known as the Neanderthal, near Elberfeld, Germany, a few miles from the Rhine, there was found in 1887, in a cave, the upper part of a skull about which a fierce scientific controversy raged for Virchow, the great German anatomist ologist, maintained that this could not be and anthrope and antiropologist, maintained that this credit not be the skull of a normal human being. But the subse-quent discovery of more than twenty skulls of the same seneral type proved that Yirobow was quite wrong. The discovery of so many skulls of one ancient type, extending, as key do, over a great stretch of time, is one of the most important features of our knowledge of principles. primitive man. Let us compare three or four of these

We may take that wonderful skull known as Man of La Chapelle-aux-Saints" as typical of the race. We see at a glance that we have here to deal with mething altogether different from the modern type man. Aithough the head is of great size with a larger brain capacity than the average modern man the skull has very marked anthropoid features. forehead is very low and retreating; the brow ridges above the eyes are very heavy and projecting; the eye sockets are enormous in size; the nasai opening indicates a very large, broad, flat nose; the jaws are prog-nathous with a markedly retreating chin.

Belonging to the same race as the man of La chapelle-aux-Saints are the skulls found at Spy, Rel-

we take the skull cap of the Java ape-man and place it beside those of Neanderthal and Spy, we see that the chief characteristics are the same in all of them, but that there has been a gradual increase in size, an evolution from the earliest Neanderthai man to the later man of La Chapelle. That they all belong to the same race is evident when we look at Prof. Boule's tracings in which they are all compared, but we see that there has been great brain development from the Neanderthai man, shown by the inner dotted line, to the heavy, black line which represents the La Chapelle man. The difference would be even more strikingly shown in a plan view of the skulls.

Now, I do not think there can be any doubt but that the Java ape-man is in the direct ancestral line of the Neanderthal man. The main features of the skulls are precisely the same. If this is so, then between the brain of the Java ape-man and the La Chapelle man we have a progressive range of capacity of from 900 to 1,695 cubic centimeters, representing an advance which probably extends over 800,000 years. This i regard as the most important evidence we possess of the essential truth of the Darwinian theory as applied to the evolution of man. But we may also approach our problem from another and totally different point of

view. It is well known to all scientific mess who have given much attention to this subject, that the lower jaw is the most important single bone in the humain skaleton, as indicating many piace in the evolutionary scale. If, for illustration, we take Frot, Kestily drawing of the Heldelberg mandille, one of the seat acclant sized Foundation human jawed ever discovered, impresented by the black cottine in the drawing; and piace a modern European jaw ever et; shown in the drawing in flat sinch, we see the meaning and ignariousness of human evolution in this garticular hostine et a gisson. If we seek conspare the Biedelberg jaw with that of the gartilla as shown in Nig. 6, we see evisit in religious

A DAME OF BRIDE

pitte are, both with rafe

is charged that the Haddelberg faw is, in some re-sis, issuries: and stronger than that of the portion, mannin, the secondary part, is wider and the doub he jaw, from the tests to the lower border, is greatat the Hudel of the jew, from the seeds to the lower border, is greated than in the portlin. But it has beeth are purch abundant, which are purch abundant, and the portlin. But it has beeth are purch abundant, and the provincing to form a chim as in modern man, alonge backward as in the aps, and the inside of the front part of the jaw, that part which lies immediately because the of the jaw, that part which lies immediately because the provincing to the provincing the provincing and the provincing to the provincing the provinc gradual, harmonious and evenly balanced modification of all the parts of an organism.

Man threw off some of his authropoid features much

ore rapidly than others. It also tells us that the orely human arrangement and form of the teeth were purely aquain arrangement and form of the teem were faily evolved at the very beginning of the Pleistocene ara. Here again we see that if Penck is right in his estimates of time, we must go back more than 1,600,000 years to find the purely authropoid ancestor of man, if evolution has taken place according to the Darwin-

if evolution has taken place according to the Darwin-ian theory.

We come now to the consideration of a paghistoric skull which is probably destined to be the object of more scientific discussion than any previous discovery in this field. I rafter to the so-called Pilitown skull found by Charles Dawson, F.S.A., F.G.R., and Dr. A. Smith Woodward, F.E.R., as Pilitown, Stussey, England.

Smith Woodward, F.M.C., at Pitthown, Summer, Engiand. This discovery, the five published "report of which appears in the Journal of the Geological Society of London for March, 1913, consists of the larger part of the skull bones and the right half of the lower Jaw.

The "find" was made in a flint-bearing gravel which has yielded some of the most aucient forms of stone implements and the teeth of sub-tropical species of als, including those the hippopotamus, an early Pliocone elephant, the mastodon and others. There can be no doubt that these remains represent a being who lived during late Photene or early Pleisto-cene times. The lower jaw ore primitive in features than the Heidel berg mandible. The pecul-iar features and relation-

ship of these two astonishing human relics are shown in Fig. 8, taken from the Journal of the Geological Soclety above mentioned. The ascending rames of the Piltdown jaw is somewhat smaller than this feature in the Heidelberg jaw, but the slope of the front part is much greater and in this respect more ape-like.

Fig. 7.—Profile drawing of the Heldelberg mandible (in malli-

contrasted with the lower jaw of

org man

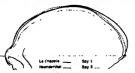

Fig. 10.—Outline tracings of various human skulls of the Paisolithic Age. (From Boule.)

Fig. 11.—The Galley Hill sons. Redown in type, Just retigated to be 200,000 years old.

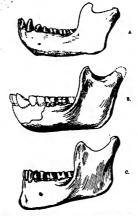

Fig. 6.—Bestoration of the Piltdown mandible (B), compared with that of man (C) and the young chimpansee (A), in left side of view.

But for the two molar teeth found in the jaw it would adoubtedly pass as the remains of a primitive anthro-id creature. But the teeth, although presenting indi-dual peculiarities which distinguish them from those yidual peculiarities which distinguish tuem irom in the Heidelberg jaw, are purely human and the variations are not greater than are found in human teeth

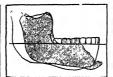

Fig. 8,-Mandibular ran superposed on seidelbergensis, that

of to-day. In Dr. Woodward's restoration of the Piltor to-oney. In 1r. woodwards restoration or the Pilli-down skull be has given a distinctly anthropold char-acter to the front teeth. In my own restoration or this mandible, which was presented before the Inter-national Medical Congress, held in London last August, this mandible, which was presented octore the ameri-national Medical Congress, held in London last August, I have represented the front teeth as of a coarse human type. I will quote my reason for this from the re-marks I made before the Congress:

"Let us consider a little the probabilities and the few facts we have concerning this dentition. It resemblee the Heidelberg mandible more than any other human jaw yet discovered, but although exhibiting much more refluement in structure than the Heidelberg jaw, it is more primitive in certain respects than that specimen. The backward slope of the front of the jaw is evidently greater than in the Heidelberg man-dible and the similar character of the lingual part of unite and the amulan character or the lingual part of the front of the jaw is even more marked. But is the variation in these two jaws greater or as great as we sometimes find in modern jaws? I do not think so, and while it may be legitimately attributed to a so, and while it may be legitimately attributed to a somewhat entiler date than that of the Heidelberg special fact, I suppose no one would suggest that it should be placed farther back than late Pilicone times. The critical question that we have to ask, then, is this: 'Is there any, reasonable probability that the human ancestor of late Pilicone times would have so anthropold a jaw as is shown in this restoration by Dr. Woodward? This teeth in the Heidelberg jaw are essentially modern in every respect and smillier, notwithstanding the concusions size of the jaw, than the teeth of some primitive races of to-day, 'don what grounds may we assume that it little farther back: we should find so similar a destition as we have been? This form in Dr. Woodward's restoration is esparated from the Heidelberg mandible untold spass. It the Heidelberg jaw is late Pilicene, the Pilideova mandible would have to be Miccone, and I confess that I de not know that we should be warranted in assuming that the human ancestor of Miccone times had a law so much like that of the modern ape swhat earlier date than that of the Heldelberg speci

It is, I believe, assumed that the common ancestor of man and the anthropold spes had a generalized form of dentition which probably resembled the present almuma form as much as the present nothropold form. We have some indications of that generalized form in Dryopithecus, Pllopithecus, and Mesopithecus. from that generalized form the human and the simian trom that generalized form more and more specialized in forms have each grown more and more specialized in accordance with the original variation—if the separa-tion of the two branches occurred in Miocene times and the specialization in different directions continued until the late Pilocene period, is there any probability that we should find this anthropold dentition after that ensely long period of progression toward the modern human?

We have, I think, a logical right to assume, in the absence of any evidence to the contrary, that the denti-tion of early or late Pilocene man resembled the human dentition of to-day as closely as the dentition of the early or late Pilocene ape resembles that of the ape of to-day. If I am right in that assumption then it is clear that the dentition of the restored l'litdown skull is unwarranted."

Since the date of that meeting Dr Woodward has found a fossil canine tooth in the gravel beds near the spot where the other portions of the skull were discovered. He claims that this tooth, which is distinctly anthropold in character, belongs to the l'llidown jaw, and that it, therefore, establishes the correctness of his restoration. Now all the other bones of this skull are of a rich brown color caused by the iron in the gravel beds, but this new discovery is of a dead black color, totally different from all the others. If this tooth was originally in the Piltdown mandible, as Dr. Woodward claims, I can think of no reason for such a strange ciaims, I can taink of no ressou for such a strange phenopenon as the marked difference in coloration, and, so far as I am aware, there is no known precedent for it. My own criticism of Dr. Woodward's restoration of the Pittdown skull was confined to the dentition, but Prof. Keith has made a very vigorous and trenchant ault on the entire restoration.

Dr. Woodward gives the skull capacity of the Plit-

down man as 1,070 cubic centimeters. Prof. Ketth continueters, or a ilttle more, thus bringing it about up to the average of modern man. The point is of vital importance in its bearing on the problem of human evolution. It seems evident at a glance that the Piltdown skull is not In the line of descent of the Neanderthal race. The supra-orbital ridges are but slightly develop the forebond is fairly full and well developed. The upper part of the head is

Fig. 9 .- Profile of the Heidelberg mandible (outline) contrasted with that of the mandible of a

therefore, according to Prof. Kelth, in the line of descent of modern man. This brings us face to face with an astounding situation. We have in the Piltdown skull the remains of a being estimated to be half a million years old, with the skull and upper part of the head closely resembling modern man, but with the lower jaw of a gorilla. We cannot escape from the fact that (Concluded on page 444.)

Fig. 12 .- The man of La Chapelle-aux-Saints. A entative of the Neanderthal race.

# Wireless for Railroad Trains

# A New System Which Secures Uninterrupted Communication at All Times

THE utility of the wireless telegraph in directing the movements of ships at sea, in communication and from ships, and in calling for help in emergencies ins been strikingly demonstrated, but it remained for an enterprising American railroad to apply wireless communication to and from moving trains. A test just made successfully on the Lackawanna Railroad on a regular express train running between New York city and Buffalo, though only a partial test in the experi-ments thus fur conducted, has shown immense possibilities of safety and time saving by insuring that trains will siways be in communication at any speed and at any distance from stations, regardless of "line breaks" from winter blizzards or from washouts, fog which obscures signals, and other extraordinary condi-

419

In the ordinary wireless telegraph system m are sent and received between stations equipped with nutcume or "aerials" supported on high towers. The Lackawanna Railroad has stations of this kind at Scranton, Pa., and Binghampton, N. Y., with a working radius of about 300 miles. But, of course, it is out of the question to place any structure such as an ordinary aerial on a rullroad train which has to pass through tunnels and under bridges, and a prominent feature of these tests is the use of a highly special serial for the train installation. Some very recent experiments, notably those conducted on November 21st and 23rd, have demonstrated that wireless ration can be maintained to and from a train equipped

with a very low aerial, viz., a quadrangic of wire supported at a height of only eighteen inches alove the roof of the car. The distance between Scranton and Hinghampton is about 65 miles, and in the experiments just made it was found possible to main-tain communication from a train running at 55 miles per hour, part of the time direct from the train to the fixed station away from which the train was speed ing; and when the train had proceeded to a point too far away for its short uerial to force signals through to this first statler direct, the signuls were de ifvered to the station by being picked up at the sec ond station and relayed back. At no time during the tests was the train out of communication with both stations in this way.

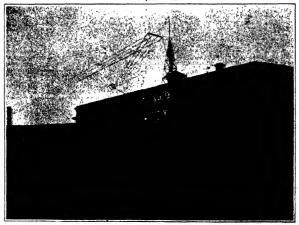

The arrangement used consists of four quadrangu lar aerials mounted on the of four adjoining cars of the train, and only 18 inches above same, as stated Each quadrangle is connected to its neighbors on the other cars by a speclai attaching ping wireless operator's station is installed in a booth in the third car of the group, so us to bring the lead fron his apparatus to the four-fold nerial at a point at the middle of same. The regular Marcoul system is employed, except that the power is furnished by a special motor-generator set driven from the regular train-lighting dynamo, and the ground connection is made to the rails by a wire to one of the cur trocks The aerial is of heavy cop per wire, and is insulated for the high sending volt nge (between 8,000 and 0,000 volts) by large porce-lain insulators mounted on iron posts at the corners of the car.

The wireless telegraph installation

Two of the cars of the wireless telegraph equipped train, showing the aerial above the car reofs and the wireless operator's cabin.

The 700-foot aerial of 300 miles working radius on the roof of the Lackswama Railroad station at

The special neefalness of the system was indicas the other day when the conductor of the train we taken ill, while his train was running at high spe-westbound. The next station at which a relief or ductor could be obtained was Scranton, 30 miles away. Ordinarily a delay would have been unavoidable—either a stop in order to send a telegram by wire asking for a stop in order to send a telegram by wire assing too a relief conductor or a walt at Squanton after arrival at that point. But thanks to the wireless telegraph equipment there was no need to take either of these measures. Instead, the conductor notified the wireless operator on the train and the latter sent a direct to Scranton, with the result that a relief con ctor was on hand to take charge when the train pulled in. In the same way an extra car, nee pulled in. In the same way an extra car, needed to provide accommodations for an unusual crowd of pas-sengers, was ordered to be in readiness to be coupled on at Scranton, thus eliminating the delay that would ordinarily have been experienced in getting the car up

Apart from this emergency value, however stration that the wireless telegraph can be depended upon for unfailing communication between running trains and fixed stations and between the trains them-selves may mean a revolution in the operation of trains comparable to that which followed the introduction of the ordinary wire telegraph for this purpose. railroads can install reliably tuned equipment whereby dispatchers and train conductors are able to keep in direct touch regardless of stops, it becomes possible

to save no inconsiderable amount of time in routine train operation-possibly stances to the time saved by regradings, cut-offs, and other improvements on the right-of-way that require auch large appropriation of central

Aerology in the Arctic THE results of the sounding-balloon observations made by the Franco-Swedish expedition at Kirupa (68 north latitude), in Swed-ish Lapland, during 1907. 1908, and 1909, have fust been published by M. H. Maurice, chief assistant at the observatory of Trappes. Not the least remarkable fact in connection with these observations is that of 72 balloons sent up, 41 were recovered, with their meteorographs. The country about Kiruna is sparse ly settled, and the inhabitants are rather primitive. Before the observations were begun, circulars in four languages—Swedish, Finnish, and two Lapp dis-lects—were widely distributed, announcing the naureu, announcing the na-ture and purpose of the un-dertaking and requesting the finders of balloons and apparatus to return the same intact to headquar ters, in consideration of a vard of 15 crowns (about \$4). Similar notices were nched to the balloons marives. Most of the balloons were returned after a considerable lapse eral years. One be into a lake, where it was recovered after three years. The bishest sittinde rec ed was 22,760 meters (over 14 miles). The height of the stratosphere was found the stratosphere was found to vary as in temperate latitudes; i. e., it is higher in emmure than in winter, and higher over stratey, closes than over

# The Panama-Pacific International Exposition of 1915 Description of the Exposition Site, the Main Courts and the Great Exhibit Palaces Hamilton M. Wright

THE site of the Panama-Pactic International Exposition lies within the limits of San Francisco, as a crescent upon the shores of San Francisco Bay, and just inside its "Golden Gate" entrance to the Pactic

No more picturesque location could be imagined. On the south, east and west the grounds are eactreled by the contingual of varying counters, rising successively from 200 to 900 feet above see loved, this the enfolding walls of a vast suphithester. Upon the north the site opens out upon the harbor of the Pround the shores of the continuation of

easered whole strates of the tooleen cute, guarantee seeks side by rugged cliffs and protected by forts.

The central portion of the site lies slightly above the sea and is encircled on three sides by gently sloping ground; within a short distance from the boundaries of the site these slopes change to steep hillides, and thus the site becomes the floor of a large amphithenter, from whose sides the exposition will be seen stretched out below. To the cest and south the residence section emired to the steep of the steep side of the steep sides of the steep side military nearwards, and to the west and southwest the site is cashraced by the wooded slopes of the Presides military nearwards, cafer with cypress and enculpries and interspersed with consaional vistas of green valleys.

and encalprious and istorrepersed with occasional vistas of green valley.

The exposition buildings were planned in great grouppage to conform to their impressive natural entroundtings on the shores of San Francisco Bay. With the material control of the shores of San Francisco Bay. With the state of the shores of San Francisco Bay. With the principation to blend with and fit into, it was felt by a sufficiently at combination to which was confided the pressit work, that only the broadest and boddest charge of conference on the shore of the state of the short of the sh The buildings are easily accessible from the courts, a fact of inestimable advantage to exposition sightseers who sometimes grow weary of the long distances to be

The expesition palaces, built upon an east and west axis, will face the bay upon the north: they will parallel the stream of the great incoming traffic of the world through the western gate of the United States. Ships setting in harbor pass before the expesition grounds where the great buildings are fast arising. The harbor itself will be a part of the great theater upon which will be staged the world's jubilee, and 4he Golden Gate will be the entrance to the theater.

A mirvelous panorams will be afforded victors on ships coming through the Golden Gate. As one books from the harbor he will see three main groups of exposition buildings. There will be the great central group comprising the fourteen exposition palaeses to devoted to general exhibits; there will be the group upon the left hand or east end devoted to ammement concessions and covering sixty-five across. The right hand group upon the Presidion military reservation and nearest the Golden Gate will be devoted to the pavillons of the States and participating nations

From afar, the central group, the main exhibit pataces, facing for more than a mile upon San Franciscoharbor, will present the offect of aimest a solid massing
of palatial structures, a great walled city, a city of the
Orient, with outside walls, as high as the average sixstory city block and with golden domes and towers
rising to heights of 200, 300 and 400 feet. Nearer at
hand it will be seen that the exposition palaces are intempersed with great open courts. Three main couris
will run north and south through this central group.
In general the buildings of the central group are to be
brought into contact with those next adjoining by
areades, courts and archways. Through this method of
freatment four of the general exhibit palaces of the
main group, fronting horth upon San Francisco Bay,
but set back a distance from the water's edge, will
present a single abrillectural design. Their walls and
the adjoining arches will form the main northern facado
of the exposition alway the shorts of the harbor, the
marveless frontage that will be first seen by visitors
who reach the exposition city by water and enter San
Francisco Bay through the Gelden Gate. By day the
gittering piltars and minarets of this mile-long facule
will be seen as a dream city, while by night they will
reflect the sheen of a million lights into the bay.

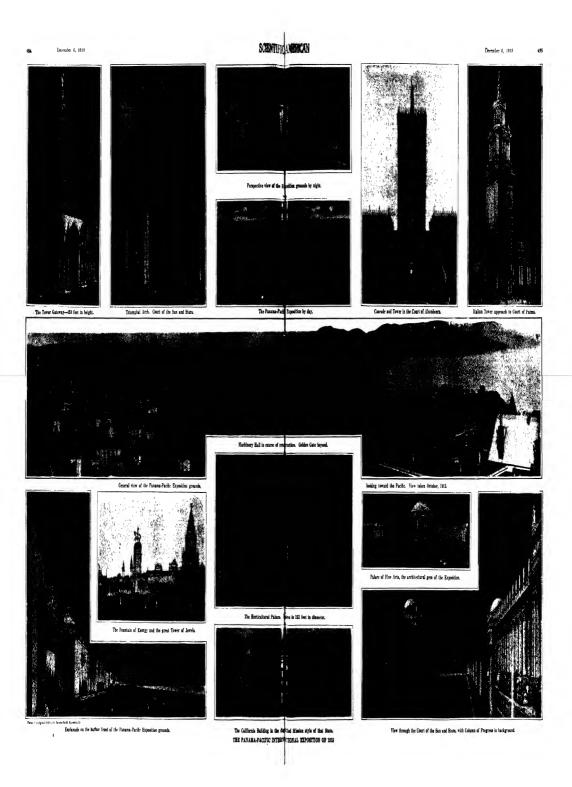

effect the sheen of a million fights into the bay. Hefore the façade and along the harbor's edge for more than a mile there will be built a great esphanade a vata stretch of ground and terraces in which four-time will play and groups of statuary he sed at intervals. Brilliant flowers and hardy flowering trees and strubs will slend warmin and color to the esphanade indeed, throughout the exposition, flowers and foliage will contrast with the shinking colonandes and peristyles and walls of the buildings, and will enhance the beauty of innumerable lagoous, fountsin and water effects. The esphanade is to be known as the "Marlna" (villa gardens)

The much groups of buildings will lie between a tropical garden or boulevard ramining cast and west alous the fringe of the billis nearest the city upon the south and the explanated along the shores or San Francisco Bay upon the north. The tropical boulevard, to be known as the "Alameda," will be eighteen hundred feet in length and three hundred feet wide; it will be glowing with fountints, lagoons, statuary, perhydres and areades, and, secluded from the winds of the bay, it will be transplanted with a production of semi-tropical trees, plants and flowers, including the orange, bannan, olive myrite, and every variety of pains. The cast end of the Alameda will open out with a please upon Van Ness Areauc, use of the principal boulevaries of San Francisco. The west end upon the Preddio will be surmounted by a commemorative arch of triumps.

The theme of the exposition, its sentjurre and mural paintings, will easil the spirit of achievement through which America has completed the Panama Canal. In the courts there will be observed monumental expressions in Greek and Roman, Oedidental and Orlental architecture. The grounds will become a vast troplet and sent tropical garden through the transplanting of palms, evergreens and flowers. A brillbart yet harmonious color scheme has been designed by Jules Guerla, one of the best-known authorities on decorative coloring in the world.

ing in the world
The prevailing color tone of the exposition will be an
ocher, a tawn; buff, several shades removed from white,
ye in the distance giving the effect of white; but it will
unt be glaving under the brilliant samight of 'culfornia,
in the courts there will be a marvious biending of
colors; Ponnelian red, strong Italian blues, vermillon
and orange will predominate. The court system is
unique in that it will permit each architect, artist or
sculptor to present some distinct canception, without
clashing with the exposition architecture and coloring

(Concluded on page 426

The main group of exhibit palaces, facing upon the

harbor for 4,500 feet, will present practically the ef-fect of a single palace. Eight of the buildings will be joined in a rectangle to form what will amount to a

#### The Grashof Medal Presented to George Westinghouse

A T the annual meeting of the American Society of Amchanical Engineers, December 3rd, there was presented to Mr. George Westinghouse the Grashof Medal, which was founded by the Verein Deutscher ingenieure in memory of Franz Grashof, the famous engineer and professor and author of many imp works and the theory of elasticity, general mechanics and machine design

This medal is given by the Verein only on recommen ation of the Council and by maniform or recommendation of the Council and by maniform who have rendered pre-eminent service in the field of engineering either in research or in practical activity. It is the highest honor in the gift of the engineering profession

Among the men who have received this honor in the Among the men who have received this honor in the past may be mentioned the following: C. von Bach, professor of machine design and one of the founders of the modern theory of elasticity and a lender in the science of testing materials in Germany; Gruson and scleence of testing materials in Germany; Gruson and Schichan, founders of immense engineering plants— metallusgical and mediane construction—and shib-build-ing yards from which some of the best German ships, both commercial and war vessels, have since best sunched; Gustav Zesues, whose contributions form such an important part in modern thermo dynamics; Carl von Lindo, one of the formoders of the retrigerating Carl von Linde, one of the founders of the refrigerating infuntry, as well as one of the men who did most for the development of its theory and the understanding of the processes leading to the economic production of cold and liquefaction of air and other gauss; Prof. Riedler, well known in the field of steam engineering; Sulser-Steiner, in whose works many new types of Sulser-Steller, in whose works many new types of Dissel engines and steam turbines have been developed to commercial success; %. Slaby, known by his work in many branches of electrical engineering; Gustav de Laval, who was also made honorary member of the American Society of Mechanical Engineers, for his in-Lavar, was was no mines morrary memory of the American Society of Mechanical Engineers, for his invention of steam turbins and centrifugal apparatus of various kinds: Hermann Biolim, one of the or of the great Blohm and Yose shipbuilding yards, spitell of German marine engineering; Frot. Aurel Sodois, one of the greatest authorities living in regard to the theory of the steam turbins, hisself an inventor; Centil Pecidiand von Zeppella, one of the most popular and-picturescue for a form to the produced the Euppella simble, the pride of the Germanian autors; Frot. Martons, a nutversally recognised authority on testing materials, and therefor of the National German Inches for the Companion of the

The State of State of

Putters Prices of Commodition and Materials By Alex. Del Mar, Fermenty Chief of Bureau of Com-merce and Navigation, United States Treasury

DURING recent years, noticeably since the opening bot the present century, a remarkable rise of prices has occurred in the Western world; the Eastern hemi-phere not being at all affected by it. Nor has the en uniformly influenced; the rice being

Western world been uniformly influenced; to observable chieffy in the four leading early seems of the seems of the contrast of of the rise thus far.

On this subject opinions have rem ably varied. In an address to the bank-ers of Minnesota, Mr. William C. Brown, president of the New York Central, himanker, attributed the rise to th increased supply of gold and to "the failure to increase the products of our farms in anything like the ratio of increase in consumption." This he thought exerted thrice the influence attributable to gold Mr. W. B. Ingalis, in an elaborate essay published in the *Mining Journal* three years ago, and guided largely by the Saurbeck (British) and Bureau of Labor (American) Index Numbers, attributed the rise "to a variety of causes," such as gold production, exhaustion of natural resources, standard of living, monopolies, protective tariffs, demands of labor, and civic congestion. Because no substantial appreciation had occurred "in the Indices of all classes of commodities," but only in se no declining tendency was

observable in the rate of discount; and because "the observable in the rate of discount; and because "the ratio of increase in gold has been less than that of iron, copper, lead, tin, and sinc," he concluded that gold, "though not without effect," had not excreted any observable influence upon prices. The principal causes appeared to be the others mentioned show, to which he also added "the demand and supply" of commodities.

In the debates attending the passage of the Payne-ddrich bill of 1909, and the Underwood bill of the present year, one side attributed the rise mainly to the tariff. This the other denied. In Mr. Payne's g

speech of May 2nd, 1910, he even cistmed that his hill, though less than a year old, had lowered the price of mests, vegetables, and other commodities, especially those consumed by the poor. His list of tariff "reductions" included 138 specified commodities and classes of commodities. He attributed the rise of prices not so much to the increased supply of gold as to the "reduced cost of gold, owing to new methods of producing it."

With great esteem for the distinguished authors of these various researches, a careful review of the causes alleged does not appear to satisfactorily account for the rise, especially for that greater rise than elsewhere which has admittedly taken place in the United States. All of the alleged causes, except the tariff, have operated in the four principal States of Europe, and even as to tariff, this has been materially raised in all of them exbeen materially raised in an of them ex-cept England. Unless by speculation, gold cannot influence prices until it is coiped into the money in which prices are ex-pressed; and none of these researches dispresset; and note of trees researches on-cuss the mint statistics, or the wast ship-ments to India, where much of it is buried in the earth. No merchandles whose pas-sage through the custom house is made the subject of a tax, pays that tax. It is the importer, the man, who pays; she the relation of his import taxes to the the relation of his import taxes to the prices of commodities is much the same as that of his excise, or itemse, or in-come taxes. He shifts as much as he can upon other people, and they shift back. The eventual result is a general diffusion of taxation. Upon a final salelysis it all comes down to the cost of government and the benefits derived from government, both studies, and Municipal; far not intensity as subject to he hurs or cise. both wedgen! State, and Municipal; far too designies, a subject to be lung on the pastgrachitusline of a tariff bill. This may do fite "politicis," but not for politicis economy. Of the other alleged causes of the time, such ine suprimitival production and commencipation, relatest resources, standard of "bring, ofte commencial and the statest resources, standard of "bring," ofte comments, necessity of the comments of the statest resources, standard of

wages, rates of discount, demand and supply, it can only be said that they are either too slow, remote, or inadequate to satisfactorily solve the pending problem of prices in the United States. A reminder of national

ditions may lead to a more satisfactory expianation. The population of this country is about 100 millions, f whom nearly 40 millions are engaged in gainful occupations which yield on the average nearly a thousand dollars a year, or 40 billions, with an expenditure of

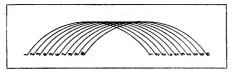

Fig. 1.—Diagram illustrating order of rise and fall of prices of various classes of commodition

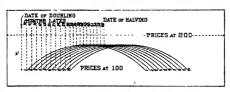

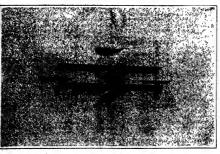

Fig. 2.—Diagram showing that a rise and fall of different prices may occur

35 billions, including about 10 per cent pald for Federal, State and Municipal Government. What has to be furnished is a cause og causes competent to explain a general rise of a third to a half in the cost of living and of probably a fourth in the prices of the commodi ties employed in the industrial arts. Such collossal sums as the above cannot be explained by any of the causes advanced; these are altogether too trifling. Something else, something hidden, unlooked for, unex-pected, must be discovered, to account for the immense rise of prices in recent years. Moreover, it must be a cause which has especially affected the United States. If under man's supervision and with no additional

Curtiss hydro-aeroplane fitted with a disk stabilizer.

In flight, without using the ailers

#### A Dished Disk Stabilizer

Some time ago there appeared he our column Aeronautica, Notes a brief description of a stabilizer had just been patented, and which consists of a disk slightly dished and mounted above the plane of an neroplane. Shortty after the Inventor of this upparatus brought in a small working model which demonstrates strated very conclusively that the apparatus would bring the aeroplane to a level position no matter in what direc-

tion it was dropped. Since then, the inventor, Mr. II. C. Flske, has had the stabillzer attached to a full-sized machine in order to prove its worth. Mr. Wiltiam 8 Luckey, of the Curtiss School, who, it with be remembered, carried off the first honors In making the circuit of Manhattau Island on Columbus Duy, fitted his machine with one of these stabilizers. It was a crude affair built hastily under Mr. Fiske's direction It consisted of a dtsk of canvas seven feet in diameter with the stdes ed upward ten inches from the horizontal at the extremities. The device weighed 11 pounds. The form of the stabilizer and the method of mounting it upon the hydro-seroplane are clearly shown in the accompanying photograph With this device Mr. Luckey made a number of trial flights, which he declared to be very satisfactory. He writes: "I find medium speed, the aeroplane very steady without use of the allerons. I also found it very effective at high speed in straight flights and medium large circles. It was not necessary in any of this work to use the alterons. The machine banked and landled very alcely in calm air and in a wind of thirty miles velocity."

One might contend that a stabilizer such as this would increase the head resistance of the machine, but it was found in actual practice that the speed was not affected materially, and if, as Mr. Luckey claims, the alterous could be dispensed with, the head resistance would be materially reduced. for the ailcrons undoubtedly act us brakes

The device is so should that it hardly needs any ex-The curve of the stabilizer is such that if tho machine starts to drop sidewise, the air banking up against the lower side of the disk will bring it back to level. When making a turn the machine banks automatically, for the interni drift due to centrifugui action brings air pressure against the side of the disk and causes the plane to lift on the outer end. Even with the crude stabilizer, the aeroplane showed a great deal of stability ugainst pitching. This could be mate-rially increased by dishing the stabilizing

disk as in the small model. Mr Luckey found that he could land or alighthe water at a much reduced speed.

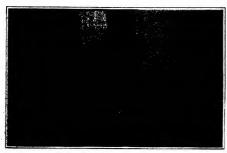

One of the accompanying illustrations, which shows the machine in flight, was which shows the machine in high, was taken after it had made a swoop from a considerable altitude in order to come down within the range of the camera. At the time it was traveling it a speed of about 70 miles per hour. Heretofore it has been necessary for the avintor to be constantly working with the allerons to keep his machine from being affected by sudden gusts of air. Apparently with the new stabilizer he need not bother with the controls and the operation of the machine is greatly simplified

#### Building the New Capital of India

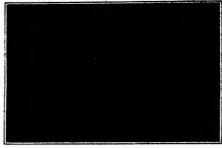

LTHOUGH nearly all the government offices in Calcutta have now been nbandoned, little progress has yet been made toward the construction of Indla's new wluter capital, which is to occupy a site of three or four square miles adjoining the present city of Delhi, and for a year or most government work is to be carried on at Simla the year round, though the viceroy and other important officials are spending the present winter at Delhi. About 25 miles of transway are being laid about the site of the new city. It is understood that the Imperial Delhi Commlitee estimates the cost of the new capital at about \$20,000,000, though the impresston prevails in India that the cost will be double this amount. About 6,000 men are now working on the site, and when the work is in full swing from 15,000 to 20,000 will be steadily employed. An incidental task will be the improvement of sanitary conditions in the old city

Lever machine for bending rails

Ascertaining the curvature by means of the bend gage.

A RAIL bending machine, in order to be thoroughly suitable, should exert a uniform bending moment of proper mag-nitude on every point of the rail. It should easily transportable, thus avoiding the peoms to be bont.

In most bending machines so far in use the rail is laid on two supports and a pres the rail is laid on two supports and a pressure exerced between these on the rail. The bending moment at the points of support thus is wil, rising uniformly toward the point of pressure, where it reaches its maximum value. It is therefore noncessary, in order to obtain a uniform bond, to shift the color of the pressure of the pressu the points of support and the point of pressure along the whole length of rail or (as in the case of bow bending machines) to apply the machine at brief intervals.

to apply the machine at brief intervals. In the new lover boulding machine de-signed by Richard Peukert, of Haida, Bohemia, the power acts on the rails on both sides, outside the points of support, and in such a way as to keep the moment between these points constant, so that the rail may be circularly bent over the whole rail may be circularly bent over the whole intermediary length. The action on the levers is exerted by a screw winoh. The leverage, as well as the pitch and arrange-ment of the screw, are so chosen that the loss of power is reduced to a minimum. The machine is operated by two men as

After the levers have been laid over the rail head at sufficient distance for the screw winch to be attached while the nuts are slackoned, the lever ends are pushed apart and the winch is drawn together by actuating the ratchet On next releasing the winch, the ratchet pawl is turned over, and the winch turned back, first by me of the ratchet and afterward with the sid of the hand wheels. The machine is ther suitably connected together by two chains and drawn forward to another working section, viz., the distance between the two lever centers. After the first operation, lever centers. After the first operation, the bend must be checked by putting on a

When using a Peukert bend gage, both the concave and convex curvature can be ascertained by determining the putch from a meter chord. The bend is then gaged most accurately by stopping the apparatus, while drawing together the ma-clime. When a certain experience has been gained, a bend, including the shifting forward of the machine, will be effected in ee minutes as a maximum.

In installing a railway a short time ago, all curved rails, (180 millimeters in height and 150 millimeters in width at the lower flange) were bent by means of the Peukert machine. The bending operations were carried out on the spot, the average daily

#### Incombustible Linoleum

THE manufacture of incombustible line leum, or, to speak more accurately, of linoleum that burns with difficulty has been a goal long aimed at by linoleum factories a goal long armed at by modelum isotories.

The attempts previously made have been based on the plan of adding incombustible matter, such as asbestos or ammonium salts, to the mass during the process of salts, to the mass during the process of fabrication. Far more promising is a new scheme, described in Technische Monste-latie, in which magnesium carbonate is added to the mass. All the carbonates have the property of giving off carbon dioxide when heated at high temperatures. This, as is well known, is a very heavy gas, which does not rise, but croeps along the floor. For this reason, in case of a fire it would stand to cut off the annuly of air it would stand to cut off the annuly of air it would tend to out off the supply of air from the imoleum. Magnesium carbonate is chosen because it breaks up at lower is chosen because it breaks up at lower temperatures than any other carbonate. The principle involved is, of course, one commonly used in the manufacture of chemical fire-extinguishers.

#### A Proposed Bureau of Labor Safety

agrees seeking to create a bureau of Labor Bafety in the Department of Labor with a special reference to investi-BILL has been introduced in Cor with a special reference to investigation as a special reference to investigation and devices. Such a bureau if instituted should give an impetus to the production and development of improvements in such devices for factory and railroad use, in fact wherever labor is employed. With and one million six hundred thousa road employees in the country, the demand for labor safety devices should be earmently developed and their introduction and maintenance strong entorous. No one is more interested in the provision of safety devices than the laborers in the particular industry to which the special devices relate and the demand sought to be created by legislation should receive attention from

#### Non-splintering Gla

VERY ingunious process for producing jahout when broken has been devised, ac-cording to Lie Nature by a Prench investor. One side of seek of two glasse plates is covered with a thin coating of galaxies, a thin clear plates of celluloid is juid between these two surfaces, and glasse and between these two surfaces, and glasse and these two surfaces, and glass and cells up then united by strong pressure integer page.

of fly, be

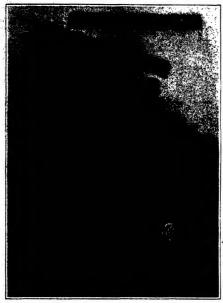

rom flying shards. .

age householder is seldon THE average householder is seldom a good inarginam and yet at any time he is fiable to have to cope with an intruder who is an expert with firestrate. Hence, it is quite essential that he be provided with seasons and the provided with seasons and the provided with seasons and the seasons has handless. The burgier usually has the advantage in knowing the general direction from which the man of the house will approach, whereas in looking for the intruder one never knows in what persistenter nook he may be liding. Revolvers provided with flash hamps have been invented which easile a man to light up a flark room suddenly and discover any intruder, but such a revolver places one at the mercy of the thick, while the light is wavering about the room in search of him. To take slam, the householder must bring his eye into alignment with the revolvers as that the hosten-holder must bring his eye into alignment with the revolvers are sensity been introduced, which makes it unsecossary for one to stand directly holitof the run. The one of the

mary for one to stand the gun. The cone of makes it unsecessary for one to stand directly behind the gun. The one of light thrown out from the searchlight conteins a black center which indicates the spot that will be hit by the builst, so that a man hiding behind a door or piece of furniture and peeping around to take size, may hold the gun far to one side, so se to mislead the burgiar as to his position. As long as the black spot is on the intruder the householder known that his revolver is properly trained. The accompanying illustration above a revolver with the improved searchlight and tabelment and also a sectional view makes it unner attachment and also a sectional view through the searchlight. It will be found to consist of a battery A, a mercury switch through the exachlight. It will be found to consist of a battery A, a mercury without B, lamp C, and leuses D and E. The lean D is perforated on se to form the dark spot above referred to. The mercury valve consists of a small giese vessel in the shape of horizontal S. Normally the drop of mercury within the vessel lies in the forward compartment. But on raising the grun sharply, it flows must the raising the gun sharply, it flows past the central constriction into the rear compertnert and closes the circuit between the lamp and the battery. When it is desired to disconnect the lamp permanently, a knurled thumb piece at the reasend of the flashlight is turned, breaking the connection between the casing of the flashlight and the rear terminal of the hattery.

#### A Gasoline Motor Plow By Frank C. Perkins

THE accompanying illustration shows a graciline motor plow designed and natruoted at Bedford, Va. The engine is

Searchlight that shows where the builet will strike.

of two cylinder type and develops nine half the time required by horses.

of two cylinder type and develops nine horse-power.

The plow is provided with a truck at-tachment and will haul 1,100 pounds up a 6 per cent grade. It steers with both front and rear wheels and with the reverse can turn as sharply as an automobile. This attachment adapts the machine for all operations from breaking the land, to the planting and cultivating of the crop and the hauling of it to market. The machine is equipped with two speeds, one for plow-ing and cultivating the other for road work and hauling, either of which can be varied greatly by the throttle at the will of the operator.

The plow pulls a two horse turning botton, outling eight inches deep and twelve inches wide. When cultivating, the cul-tivators are hooked up behind with a jointed lever, the small rear wheels out in one direction and the front tractor wheel one direction and the front tractor wheel in the opposite direction, and the machine is turned short, at the end of the row. When breaking land with a turning plow, to make the quarter turn at the corners the plow is roversed three or four (set, in which space it turns shorter and in about

half the time required by horse.

The motor of the plow can be thrown into and out of gear and the speed regulated without letting go of the handles. The two, large, spiked drive wheels pull the plow, large, spiked drive wheels pull the plow.

The plow holds the drive wheels to the The plow holds the drive wheels to the ground and the spikes prevent them from alipping, so that the machine works equally well in sod, soft ground, loam or sand. It is a practical machine in rough land. When the plow strikes a root, stump or tight rook, instead of straining or jerking as horses would do, the spiked wheels slide and the machine, but the spiked wheels all desired the machine, but the spike and the machine can be thrown out of gear instantly. It is then easily raised by the handles, as quickly thrown in gear again,

and passes over the obstruction.

Included in the attachments used with the plow are the turning points for breaking land, a seeder for planting corn, cotton or other seeds, dropping them in rows or hills, other seeds, dropping teem in rows or nils, cultivators, which include discharrow, weeders, listers and sweeps. A spraying attachment including tank and pump, may be mounted between the handles for may be mounted between the hardles for spraying trees, or crops in rows and potent spraying trees, or crops in

bar and rake attachment will prove useful in harvesting small crops of hay, clover,

#### A Three-Axle Water Ballast Motor Roller

ONE of the most outstanding features of the recent international Roads Congress Exhibition held in London, was Congress Exhibition held in London, was a new type of water ballast motor roller. The distinguishing feature of it is the introduction of a third axle and roller. It is the joint invention of Col. Crompton, the eminent British motor and road

con, the eminent British motor and road authority, and Mr Tapp.

The three-axle roller is designed ex-pressly to produce a level or regularly surved surface, as free as possible from the harmonic recurring waves or depressions which may occur to some extent with the ordinary two-axle roller.

essential feature of the invention comprises the three cylinders filled with water, carried on three axles and at-tached to a rigid frame. The general disposition of these rollers may be gathered from reference to the accompanying il-lustration. It will be seen that the frame lustration. It will be seen that the frame ends in a pluce at either extermity to which the outer rollers are attached, and both are steering cylinders, the rear cylinder moving relatively to the front cylinder. Only the center roller, which is the driver, is spring mounted.

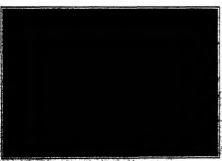

The motion of the driving central axle

in an upward direction is limited by stops which can be brought into action when and as required, the roller then being free to fall below, but not above an adjustable fixed point relative to the two end rollers. The adjustment of this point and varia-tion in the distribution of the weight tion in the distribution of the weight upon the three axies is effected by means of a special form of screw adjustment operated by the hand wheel on the frost fork head carrying the leading roller. The total weight of the roller, shown in the illustration, in light running order without water ballast, is 22,384 pounds.

With water ballast in the rollers and a full tank the total weight is increased up to a maximum of 27,600 pounds. But the to a maximum of 27,600 pounds. But the weight is distributed in such a way that at no time is the weight on the front roller less than 1,904 pounds in excess of that imposed upon the rear roller, this being necessary to prevent both front and rear steering rollers from leaving the ground.

The adjustable variation in roller pressure enables a single roller of this type to carry out the work of both light and heavy rollers of other types, and makes it eminently suitable for rolling asphaltic or tar-macadam surfacing materials, the minumum rolling pressures being utilized minimum rolling pressures being utilized during the early passages of the roller over the surface, while for final consolidation the rolling pressure can be increased up to any desired extent within the limits of the machin

harmonic waves in the rolled surface he-catus, in passing over the ridge of creek of a wave, increased pressure is brought to bear on the road surface at this point matically by the center roller, fo automatically by the scales roses, acrong the surfacing material down into the hollow or depression, over which, by virtue of the spring action, the roller then passes ased rolling pressure production of harmonic wavy st production of marinoms wavy surfaces is obviated still further by unequal spacing of the three axies, the distance between centers of the front and center axies being greater than the corresponding distant between centers of center and rear axle.

#### Notes for Inventors

Notes for Inventors 
Photographing the Band-master for the 
"Movies."—Fatent No. 1,069,221, to Jacob 
Beek, Munich, Germany, provides for 
synchronizing a moving picture and a 
musical accompaniment thereof by photographing on the film the performance of 
the actors and simultaneously photographing on the same film a refected front view 
of the band-master directing the musical 
accompaniment. The band-master shotograph is of disposed that it may be obscured 
from the front of the access and shown a the front of the screen and shown at the rear, so that the photographically reproduced leader may direct an orchestra or band located in the rear of the picture.

or band located in the rear of the picture.

A Two-part Buttle.—A divided bottle has been patented, No. 1,064,442, by John E Cadigan of New York city in which the bottle is composed of top and bottom parta, the top part having a neck and being open at the bottom and the bottom part being open at the top and a central part which forms the bottom of the top part and the top of the bottom part has ular grooves to receive the respective parts.

Paper Overshoes.-Morris H. Siegel of New York city, has secured patent No. 1,008,942, for a shoe whose sole, side, toe 1,008,942, for a shoe whose sole, size, toe and heel pieces are made in one piece from paper with each side piece folded about opposate the ankle to provide grow sections which may be folded to contract the open-ing in the shoe to hold it upon a shoe on which it is fitted, means being provided for fastening the gore sections when so folded.

A Reinferced Kinematographic Pilm. Charles Dupuis of Charanton, France, has secured a patent, No. 1,068,747, for a kinematographic film, It consists of a band of strong paper baving openings and photographs on gelatine in and openings so that the film is of uniform thickness throughout, the feeding perforations being cut upon the edges of the paper in prope relation to the images.

A New Base-ball Score Board.—In a patent, No. 1,069,920, George S. Coleman of Washington, D C., shows a score board provided with representations of a human figure arranged in succession. Light may pass through the figure. Attitudes may be assumed which correspond with those be assumed which correspond with those of a player while in the act of moving from one point to another. An illuminating device is passed in rear of the representations in succession to produce the effect of a person moving in the direction of the series.

Combined Can Opener and Pouring Spout.—In a patent, No. 1,069,388, Lewis Colwell of Chicago, Ill., shows a can-puneturing and pouring attachment in which an annular band in sections has one of the sections provided with spurs to or the sections provided with spurs to puncture the can, another section pro-vided with a pouring spout, with a outter adjacent to it to puncture the can forming an outlet to the spout and with levers connecting the sections so that they can be drawn together to secure an opening of the can.

of the can.

Living on an Expired Patent.—A Washington with when recently asked what a friend, who ched out a presentious living, was deciag, replied that be thought he was "living on an expired patent." He will denty thought this was funny, and did not realize how many people made very good livings indeed out of expired shares the large where the another them and the write recalls inpasses where the inventor made more money out of the invention after the petents superior than the control of the patents.

The control of the patents with the inventor after the petents superior than the inventor after the petents superior than the inventor after the petents superior than the control of the patents.

Pertaining to Appeared.

SOLE BRIDGE.—5. D. Marsawer, 90 John St. New York, N. Y. The primary object here is to so improve arth supports or bettigns of hoster and shoots as to make them obtaped in construction and more efficient to two than devices herelefore proposed for this purpose. The main portion is made of word, and hence the charge, light and region and possessed of sufficient strength to resist beauting of discrete strength to resist beauting or discortion.

HOBIEST.—D. O'DONALIS, 550 W, 371st St., New York, N Y. The object here is to provide improvements in knit socks, stockings and like knit articles whereby such articles can be assily worn and held up in proper position without the use of separate devices such as garters, bees supporters, and the like.

Of General Interest,

VERTICAL PILE FOLDING.—M. B. Jack
nos, P. O. Drawer 788, Victoria, B. C., Canscia. Among the objects here is to provide a
filing device which will reduce the tendency to
mindle papers, means being provided as to
necessitate the opening of the file in order to
introduce additional papers, but which locking
means is of such a simple nature as to require but a moment's time.

quire but a moment's time.

STILL.--II. B. PHILLIPS, Pairmount, N. C.
The invention pertains to improvements in stillin more especially those used for the production of turpeculae. It provides a device in which pine wood containing turpeatine may be treated without any danger of overheating the wood. The device is of a portable nature and may be readily set up in one section and moved to another.

ARTIFICIAL BUTTERPLY.—P. SERLINE, New Kenslagton, Pa. The purpose of the lavest-or is to provide a construction in which a but-terfy may be caused to take substantially any pose and be revelly second in place whanever desired. Another object is to form artificial butterfiles of various colored cloth or other material, so as to match with different am-

ronndings.

POST ANCHOR.—F. T. Ballar, Newport.

R 1 The intention here is to provide an enboring base for posts which may be readily placed in position on posts, the parts being so formed as to require a minimum amount of work in essembling and properly positioning the posts and anchors in the ground.

the posts and anchors in the ground.
BRUSH - A. L. Riotzwaw, 1824 Chestmi
St. Pbiladeiphia. Pa. The Invention provides
a brush arranged to permit the user to con-veniently and quickly replace a worn out bright holder by a new one and to silow thorough cleaning of the holder and the support thereof with a view to keep the breash at all times it

DIOR LOCK—F. Watern Westernville, N. Y. This invention relates to improvement in door locks in which the door is made to one and close simply hy a slight push or pail ou lie handle, and can be attached to or re-moved from the door more simply and more easily than the common lock.

Heating and Lighting.

RESTREY WATER IN SATER.—R. C. BOYER, 1985 Pepper Ave., Lincoln, Nob. The exacutal object here is evolved in the provision of a heater which include in part an agrangment of circulating coils of play on an arrangment of the country of the control of the country of the control of the country of the country

manenanes and mechanism Sevices.

RELL.—J. Porcours and L. Rozziko,
care of improvided Mrg. Co., 32 Union Square,
Now York. N. Y. This larestion relates to improvements in bella, and has for an object to provide an improved structure of single, strong construction with a disfumm number of parts and positive movement of the articles members upon the actuation of the operating hostory.

botton. PLUMB BOB.—J. Gambians. Twonfy, N. J. An object of the inventor is to provide a bob, the body of which is adapted to bouse the cord by which the bob is -uspended while is use. Another is to improve the construction whereby the drum on which the cord is wound whan bound within the dwive may be supplying which is to withdraw the cord, to return the cord into the bob, or to lock it at all options the cord into the bob. or to lock it at all options the cord into the bob. or to lock it at all options in the cord into the bob. or to lock it at all options in the cord of the cord in the

MOLD FOR MAKING CONCRETTS WALLS,

—B. A. ISLER, 566 BEASOOK, Br. BROOHER,

N. N. Y. This ferrestion certains particularly
to a machine or mold for use in the forming
of concrete force, watin, partition and the
walls of the mold are raised successively as the
walls of the mold are raised successively as the
wall is builty up in Eddenses, and may or may
not be supported by the lower portion of the
wall already result.

Pertaining to Betreat

Pertaining to Becreation.

RATE CLAMP.—T. Rearc., 146 Greenwald

St., Bine Island, Ill. The object been in to so
construct the clamping mechanism of a roller
shate as to produce an article combining the
chements of strength, despuses, reliability and
case of manipulation, having reference particularity to the bracing consection between the
champing screw and the means for supporting
the front wheel saids.

Portsinter to Validas

Percassance to Vabioles.

WHEEL WITH MULTIPLE AND BALANCED SIME—H. LOTTE. 4 Rec Pascel
BOUNCY, 81. Sent d'Angli, Charents-Indefrours, Prance. The invention relates to improvements in the wheel with multiple and balance rims making the subject-matter of the
United States pasced applicates find December, 1907. The wheel comprises a main rim
and auxiliary rims connected to the preceding
one pair in connected to the preceding
one pair to capacity of being displaced vertically and horizontally relatively to the main
rim.

ATPOMATIC JACK—J. T. Dixcox. 11 Red.

rim.

AUTOMATIC JACK — J. T. Dillow, il Reed
St., Port Chester, N. Y. The sobject in view
in this lawrition is to provide an improved
construction and arrangement adapted to be
secured to the axies of an automobile or other
vehicle for acting in a plumitty of capacities,
as for instance a jack, an emergency wheel,
and a turn habs.

DEMOUNTABLE RIM.—W. F. JERKINS, 900 E. Clay Rt., Richmond, 'Va. This device is of simple construction. but will positively hold the demountable rim in place when the latter is secured to the fixed rim. The lawsition provides a demountable rim which is split at one portion thereof, with means adjacent to the split portion for drawing the latter tightly together and firmly holding, it is place.

ughtly together and firmly holding it is place.

CARDUBETED:—W. Excit. 107 Shockers
Rt. Winchester, Ky. In the carbareter parantdo by this leventor a vaive chains and cylindrical vaive are provided being both formed
with annular series of air inlosts and annular
series of fuel inlets, and admission to those
inlets is controlled by the movements of the
vaive bongitudinally, as governor being providest action of the control of the control of the
opposite direction. The air and real admitted

The Origin and Brointies of Mea

this introduces new problems line our study of human evolution. It shows that evolutionary changes are not correlated in the human organism. That, of course, had been known before; but no such strik-ing and radical illustration of the fact

ing and radical Hustration of the fact has ever previously been discovered. It undoubtedly suggests that costain changes may occur comparatively weldenly according to the mutation theory of DeVrisa. This, and the fact that such highly developed skulls as that of the dailter Hill man mentioned at the opening of this paper existed 290,000 years ago, force ms to conclude that there have been according to the contract of the contr andden changes somewhere in the course of man's evolution, or that his origin as man must be placed back into an abyse of time that it is appailing to contemplate.

#### The Enlargement of Sculpture

(Concluded from page 436.)
point and so adjusted that no matter her the arms move these two points slways remain in the same straight line with the fixed point. These two movements—of the shaft and of the arms—make it possible for the extremities of the arms to touch any points whatever even in a compli group and its enlargement.

When the small plaster model has been put in place and the armature for the enlarged figure constructed and the core built out to within about two measure or its finished size, points are marked on the small model, many or few, according to the amount of detail. When the finger of the shorter arm is placed on one of th marked points, the finger of the other arm will indicate the corresponding point in the enlarged figure. A long, stender nail the enlarged figure. A long, stender neal is then driven into the eularged figure so that the head exactly touches the point of this honger arm. The number of point-that must be taken depends upon the amount of detail. But if the enlargement is of a head, for example, many points must be taken about the face when there is a great amount of detail. The sculptor fills in with clay, plasteline, or plaster, being guided in finishing the surface by the heads of the slender nalls Having thus the general form of the figure he can finish details of the surface as he desires. Both the plaster model and the armature of the culargement are m to revolve on parallel, vertical axes, and the mountings are geared top chain and sprocket, as shown in the draw in a range of the pointers.

The inventor of this enlarging device is the sculptor, Mr. Robert Paine, whose art education was received in Chicago and New York. He is now engaged in supervising the enlargement of sculpture at the Panama-Pacific Exposition

it was while Mr. Paine was an assist-ant of Augustus St. Gaudens that he beand of Augustus NI Gaudens that be be-gain to work on the problem of ealera-ment. The old method was very slow, consequently expensive; it was difficult to find men who could use it successfully; even in the most skillful hands the process did not produce an enhargement in the exact proportions of the original figure. It was suprovinate at hest. Sculptors had suffered much because of poor enlargements. One large figure was actually abandoned by St. Gaudens. The layman does not realize how many

chances there are for the sculptor's work chances there are for the sculptors work to, he spotled after the clay model leaves his hands. The plaster molder may after it—then the enlargement may be misus-cessful and again the plaster molder has cessful and again the passter molec new his turn and finally the stone curver. It is very different from the old time when one man alone saw the work through from start to finish—from the conception of the start to missim—from the conception. Of the incident of the conjulered marrie. The 'no-tion' of the statue is so important and so difficult to reproduce by the old mixth and that if for no other purpose these indicates up the armsture the pointing constitute is being being the constitute of the constitution of the constituti

invaluable.

#### Future Prices of Commodities and Materiala

uded from page 437.)

personal effort, the yearly agricultural, mineral, and manufacturing output could mineral, and manufacturing output could be doubled, it would raise the rate of in-terest; seeing that by investing in pro-duction, the capitalist could sarn twice as much as by lending under present cir-cumstances. Similarly, if a means were invented which would cashle two pay-ments of money to be made with the same capital and in the same time in which only one payment can now be made, the effect on prices expressed in money would be the same as though the whole sum of money in circulation were doubled. It would infallibly operate on prices as did would infantily operate on prices as that the issues of green-backs half a century ago, or as we feared the full-tender silver dollars would operate in 1872, when we restricted their mintage and (for a time) limited their tender.

It is believed that the cause has been found not that it has doubled, or is go ing to double prices; but that it has sericountry; and is likely to affect them still further in future. The cause is the telegraph and telephone lines, which, owing to their enormous and exceptional incre in the country, have multiplied the meaus in the country, have multiplied the means of communication between distant per-sons in business, enabled a single dollar of money or of credits reduced to the velocity of money, to do as much work in making payments as formerly one and a third, or one and a half, dollars could do: thus rendering dollars superabundant and begging for exchange or investment at necessarily enhanced prices for commodities. For be it observed that not only have commodities risen: so also has the rate of interest for permanent loans of

If we divide commodities into ten marketubility, it will be found that they do not rise simultaneously, but one after another, somewhat as follows: 1, shares another, somewhat as follows: 1, snares in industrial enterprises, with international market; 2, shares, with local market; 4, staples, cotton, wool, tobacco, etc.; 5, merchandise, contractors' materials, ste. t 6, fabrics, machinery, etc.; 7, real estate; 8, skilled labor; 9, unskilled labor; 10, professional services. When the cause of the succeeded by opposite influences, for ex-ample, a shortage of the current gold supplies, such as that which occurred in 1825 45, the fall of prices would take place in the same order. Fig. 1 shows both rise and fall.

If (for the sake of further illustra-tion) the increased velocity of money had the effect to double prices in 60 months (5 years) and was followed by circumstances tending to restore them to their former level, then it would be seen that while some prices were falling, due to the assumed gold shortage, others, from the influence of the previous "velocity," would still be rising. This curious movement is shown in Fig. 2. Though the in Tooke's "History of Prices." This phenomenon, the velocity

This phenomenon, the velocity of money, was observed by John Looke, Henry Thornton, John Stuart Mill, and numerous other political economists of the past two centuries, though owing to the imperfec-tion of data, none of them essayed to comtion of data, none of them essayed to compute it even approximately. In 1894 it was computed for the United States by the writer at about two transfers of the dollar per west fer bombined money and credits, after the latter had been reduced to the velocity of money. It is now probably one transfer in three days; money much more active, while credits, as a

S TATISTICS of the olicloth and line eum industry in the United States for Don are presented in detail in a bulletin soon to be issued by Director Harris of the Bureau of the Census, Department of Commerce. It was prepared under the direction of W. M. Steuart, chief statistics for manufactures. tician for manufactures.

This industry embraces establishments ugaged primarily in the manufacture of floor coverings of olicioth and lineleum (including cork carpet) and of enameled oficioth, including table, shelf, and uphoi-steress; olicioth, etc. Some of the estab-lishments in the industry also manufacture buckram and burlap wall coverings.

#### Value of Products.

The value of products of establishments in the United States engaged in manufacturing official and linoleum in 1800 was \$23,339,022, two thirds of which (\$15,550, 101) represented the cost of materials The value added by manufacture (value of products less cost of materials) was therefore, \$7,788,921. The olicioth and linoleum branch of the industry contriblinoleum branch-or the industry contrib-uted 67.8 per cent of the total value of products reported for the industry as a whole and 72.7 per cent of the value added by manufacture. Of the total number of wage earners, 81.2 per cent were reported by the floor oil-cloth and linoleum branch.

by the floor cil-cloth and linoleum branch.
The manufacture of ollcloth in the
Linited States commenced about 1807.
Statistics for the industry first appeared
in the census reports for 1810, when one
establishment in Philadelphia was reported as engaged in "Sonr cloth stamping." Its product was grien as 1,500

ing." Its product was gardy yards, valued at \$5,000.

The industry has shown continuous and substantial increases for the entire period since 1869 with the single exception of the decade 1879-1889, when slight dees appeared in several of the principal items shown. The value of products for 1900 was more than five times that in 1860, and the number of wage earners in-1869, and the number of wage earners in-creased 286.5 per cent between those years. The value of products and cost of mate-rials more than doubled during the decade 1869-1809. The percentage of increase in each case being slightly less than during the preceding decade. The number of wage earners increased 61 per cent and the amount paid in wages 73.5 per coffrom 1899 to 1900.

In 1899 the imports of elicioth and lin deum amounted to only 416,658 square gram amounted to only a10,000 square pards, valued at \$218,210, but increased steadily from year to year until 1807, when 7,109,067 square yards, valued at \$2,318,772, were reported. From 1907 to

89,313,772, were reported. From 1007 to 150 the imports decreased to 4.445,615 square yards, valued at \$1,234,560. The value of the exports of oll-oloths has also increased with each successive year, with the single exception that there was a decrease in 1000 as compared with 1008, and was hore than four times as great in 1500 as in 1508.

Mallet-type locomotive fitted with mechanical stoker; built for experimental purp

## Stoking the Locomotive by Machine

#### A Large American-built Mallet-type Locomotive for South Africa

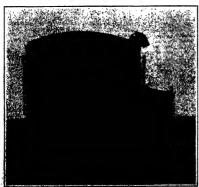

THERE has recently been introduced on the Union I of South African railways a large 2-6-6-2 Mailet type locomocities, built from the designs of Mr. D. A. Heedris, the chief mechanical engineer of the South African railways, to serve experimental purposes. The engine works on the compound system, and has no superheater, while the driving coupled wheels of the high and low pressure engines are of different sizes (3 feet 10 inches and 4 feet 3 inches diameter, respec-(a reet a) increes and a reet a) increes cambeer, respec-tively), in order to increase the hauling cajacity on the heavy gradients. The engine has a total heating surface of 33,385 square feet with a grate area of 49.5 square feet and a tractive force at 50 per cent cut-off. square feet and a tractive force at 50 per cent cut-off, of 45,000 points. The wheel-base of the engine is 41 feet 6 inches, and the total wheel-base of engine and tender 66 feet 9 inches, while the total length is 74 feet 10% inches and the beight from rail level to chimney stack is 12 feet 10% inches. In working order the engine weights 105 tons 2 hundredweight and the tender 60 tons 17 hundredweight.

The most interesting feature in this Mailet type of

locomotive is its equipment with the "Street" mechanilocomotive is its equipment with the "Street" mechanical stoker, the satient features of which are shown in the pictures at the bottom of the page. The tender is of the ordinary type, carried upon two 4-wheel trucks, It has a carrying capacity of 4,000 gallons of water and 10 tons of coal. The tender is first with a crusher of the moving jaw type, worked by an engine placed behind the brake pillar. The fireman showless the coal into the hopper of the crusher, which reduces it to a uniform size. The coal fails from the crusher, through a chute, into a receiver fitted behind the drawbar of the icomotive, wheen it is picked up by byteket workthe locomotive, whence it is picked up by buckets worknie accomotive, weenee it is picked up by buckets working on a beit in the pipe and is discharged into the central hopper on the firebox above the firebole door,
The buckets rise full on the left-hand side, and are
worked by another small engine placed on the top of
the firebox on the left-hand side.

There are three delivery pipes from the central hopper to the inside of the firebox. The delivery of the coal is controlled by three steam cocks operated by adjustable cams on the main shaft of the auxiliary engine, and can be directed, by means of a conical tray, either to the middle or to the right or left coal-feeding pipe, whence the fuel is blown into the firebox by the steam jets, the force of which is regulated by the to deposit the coal just where it is required

While it is premature to discuss the merits or otherwise of this stoker, it is claimed to have given better results, so far as locomotives are concerned, than any that have yet come under notice—it is undoubtedly a compileated machine, the fireman having to attend to two auxiliary engines in addition to handling the same amount of coal. Of course the labor of shoveling from amount of cost. Of course the labor of shaveling from the tender into the firebox is avoided, but every outne-of coal burned has to be transferred by hand to the crusher. A very noticeable feature of this delve is the noise. First there is the crusher working at a rapid rate, next the circulation of the conveyor belt, and finally the Maxim gualitie reports of the steam cocks. controlling the feeding, which all tend to contribute to produce a racket that is deafening to one who is unaccustomed to the working of the machine.

Forward and of tender showing the coal crusher.

The purpose of this fournal is to record accurately, simply, and interestingly, the world's progress in scientific knowledge and industrial achievement.

#### Scientific American in the Schools and Universities

F the material which comes daily to the Editor's desk, not the ieast interesting and valuable is the correspondence of what might be called a the subject matter that appears in our columns. Of an editor realizes how difficult it is to keep in clo touch with the needs and tastes of his readers; and cer tainly none knows better than he how great is his desire at all times to gather just the kind of information which is desired, and present it in a manner which shall b at once illuminating and agreeable. The aim and scope of the Scientific American is stated exactly in the opening italicized words of our editorial columns: "The of this journal is to record accurately, simply and interestingly, the world's progress in scientific knowledge and industrial achievement."

Occasionally our readers are moved to write and tell

us how far, in their judgment, we are succeeding in our task as thus set forth; and always these comments are valcome, and always the suggestious which have practical value are noted and, as far as may be, follo

We have been much gratified at the widespread interest which has been awakened by our recent contest relative to the Ten Greatest Inventions of the past quarter of a century. We have received many letters from widely scattered localities and from people in diversified walks of life. Thus the professor of English at one of our universities writes us: "The Freshman English in the Nebool of Mining and Engineering of this university has been in my charge for some time At present I have nearly one hundred students enrolled In looking about for an interesting sub ject to begin the year's course, I noticed the contest you have been conducting in regard to the ten most important intentible devices. I asked the class to write papers on this subject and to select the one device which might be considered the most important. It may interest you to know that I received more papers or the subject of the wireless telegraph than on any other invention.

showing that the SCIENTIFIC AMERICAN straying very far outside of the lines which it has laid down for itself, we quote again from the same correspondent: "I have required the students to select some technical magazine for reading during the year, to enable them to keep in touch with the present state of progress in the field in which they intend to carry on their life work. Out of the one hundred students curolled in the Freshman English class, forty-three express their preference for the SCIENTIFIC AMERICAN.
We shall have monthly reports of the leading articles in your paper, followed by some class discustile majorial thus presented."

Apropos of the above we publish the following ex-tract from a letter received from the vice-principal of a high school in California: "May I express a word of appreciation for the great help which I constantly get from the Scientific American in my work as a scienteacher? My inhoratory is equipped with a baloptic with which we can project opaque material. I find your journal the best available source for good illustrations on live topics in all branches of high school science Nearly all of the pictures can be readily projected as they stand, but, where details need to be brought out or the cut is too dark, it is an easy matter to retouch them. Why would it not be a paying proposition for you to feature such work for schools? An increasingly large number of schools are equipping for opaque pro-jection work, and 1 am sure that the large army of teachers and students of science among your readers will gladly welcome anything which will make their work easier and more efficient."

Another correspondent writes us: "I have read with Another correspondent writes as a hard area much interest the matter in your current issue relative to the ten greatest inventions, and it seems to the writer that the result of your efforts is worthy of a more account of the contract of

normanent presentation from an educational standpoint, than the series of essays will attain; the tender you this suggestion." Our correspond Our correspondent goes on to propose that plates suitable for framing should be prepared, both of the inventors and of their principal inventions, and that these should be used to decorate the walls of classrooms in our public and high schools, taking the place of the less appropriate illustrations with which these walls are covered, and in some cases distinured

Now, although it does not come within the proof such a journal as ours to do work of the kind sug-gested, our correspondent has raised a question which we commend to the school boards throughout the country. In an age so thoroughly scientific and technical as this, the average mural decorations in our public and high schools are sadly lacking in that apparents and deep interest which modern facilities it so easy to provide.

#### Twenty-five-knot Battleships

The have been requested by a correspondent to give some description of the latest type , of British battleship of 25 knots speed. e respects these are the most remarkable fighting nodern times; for they combine with the speed of the cruiser a battery of guns of exceptional size and of the cruiser a battery of guas of exceptional size and power. The programme of the British navy for the year 1012-1013 called for five battleships of what is known as the "Queen Elizaketh" class. Not much has been published about these ships, nor is it generally understood what remarkable vessels they will be. It is our opinion that they will not be repeated in later classes; and indeed it is stated that aiready the British Admiralty have decided to return to a ship of smaller displacement and more moderate speed in their programme of construction for the next year. The "Queen Elizabeth," according to information published in British technical journals, is 640 feet in length over all, which brings the ship, at least so far as her length is concerned, into the cruiser class. Her displacement is io be 28,000 tons. The ship is to be equipped with Parsons turbines capable of developing about 50,000 horser, and this, in view of the great length and fine model of the ship, is expected to give her a speed under ordinary conditions of 25 knots, which, as everyone will recognize, is something altogether unprecedented in a bettiechle.

The armament also marks a great departure from existing practice. She is to carry eight 15-inch guus mount-ed in four two-gun turrets, ail placed, according to the American system, on the longitudinal center line of the ship. The 15-inch piece is a most powerful wear it weighs 90 tons and fires a projectile weighing 1.950 pounds. How great an advance this is will be under-stood by comparing its dimensions with that of the 12,5 inch gun, mounted on the latest ships of the British navy, which fires a projectile of 1,400 pounds. weight of the 15-inch gun is 96 tons, as against a weight of 76 tons for the 13.5-inch gun. The muzzle velocity is not high, being only 2,500 feet per second, but the energy is over 84,000 foot-ton

The armor protection will be just under 14 inches The armor protection will be just under 14 inches for the water-line belt and somewhat heavier on the turrets, slightly exceeding in this respect our own Newada" and 'Wichinburs', which hitherto have been the most heavily protected ships in any may. The "Queen Elizabeth" and her four sister ship will carry a secondary battery of skreen, tifty-esliber 6-inch guns, and side will sain mount guas for protection against a shade will sain mount guas for protection against airship attack from above. We are not surprised to learn that this class of ship will not be reprised to learn that this class of suip will not be re-peated in the British navy. The large amount of weight which must be allotted to the motive power, in order to secure 25 knots, might better be given to the armor protection or gams. This would be in line with the policy which we have steadily; and as we believe very wisely, followed in our own navy, where the speed is moderate and the armor and armament very powerful.

#### Universal Time Keeping

HE achievement of regular wireless or tion between the station on the Eiffel tower in Paris and the navai radio tower at Arlington Virginia, transmitting time signals between the two sta tions, marks an important stage in the progress of accurate determinations of longitude. For a number of weeks experiments were conducted in the transmission of these signals before satisfactory results were attained, but after interfe able, it was found prale, it was found practicable to make ats between the clocks of the Paris a d the Paris and the War ton observatories for serton observatories for several mannes. This result was reached on Novamber 20th, 1918, a date which may well be compared with September 18th, 1764, when John Harrison demonstrated the successful operation of his chronometer.

or his caronomores.

The joint work of the French and American commissions for the determination of longitude will now go forward with increased efficiency, and a higher dependency of precision in the determination of many positions. may be expected, to say nothing of the possibilities for the development of greater accuracy in navigation.

ANY LIVE CHEVENOPHERS OF GREET ACCUPACY IN INVIGATION.
It was long understood that differences in longitude, being proportional to differences in time, needed only precise and accurate timepieces for the solution of this most practical problem. Newtron usped the necessity for the development of a reliable chrosometer, but it was not until Harrison produced his instrument that a definite commercial device was offered. It is generally understood that the principal improvement in timepieces introduced by Harrison was that of the compensating balance, enabling temperature errors to be reduced to a minimum, but it is believed that another point was a minimum, but it is believed that another point was developed by Jim which is of much wider importance than appears in its use with the chrocosseter. Ordi-narily it was assumed that the great thing to be at-tained was a timepiece which should have a very sansil arror, or in other words, a watch which should beep vary good time. The navigator, carrying such a watch would always have with hint the time of a definite position, such as Greenwich Observatory, and by determintion, such as Greenwich Conservatory, and by determin-ing his local time by observations upon the sun or stars he could thus find the difference in longitude between his own position and that of Greenwich, allowing fifteen degrees for every hour, or one degree for every four minutes of time difference.

Harrison knew, what every instrument maker now realizes, that it is impracticable to make an instru-ment which shall be without error, but he also appreciated the most important fact that while he could not make an erroriess instrument, he might make one of which he could make an exact determination of the error, which was just as good. He thus set himself about to make a watch, not to keep absolutely correct time, but to have a uniform rate of error. A chronometer which loses precisely two seconds a day is as good as one which does not lose at all, since the correction of two seconds for every day enables the correct reading to be made for every day of the voyage. Since Harrison's time the chronometer has been much improved, but the reduction in the time of voyages has also made the necessity for long time corrections less necessary. Since modern vessels carry several chronomers, any serious deviation from the uniform rate is readily detected, and the unreliable instrument elim-

The most interesting example of longitude determina The most interesting example of longitude determina-tion by the use of the chronometer is associated with another scientific development which was far from be-ing appreciated until long rewrs afterward. When the "Besgle" isft England, in December, 1831, her com-mander, Captain, afterward Admiral Pitracy, was the prominent scientist on board, and the principal equipment of the ship was supposed to be the twenty-seven chronometers, carefully rated; the voyage being under-taken principally to determine the longitude of numerous islands and other points in the south Atlantic and

The important work thus accomplished has been somewhat overshadowed by the fact that the young naturalist of the expedition, Charles Darwin, whose work was cally an afterthought, employed his opportunities so well that the appearance of the Origin of Species, twenty-five years later, is usually coupled with the idea of the voyage of the "Besgie."

of the voyage of the "Bengle."
With the development of the electric telegraph the
determination of differences in longitude of places between which wire could be run, became a simple operation, show the volotity of time communication, became
so great as to superfind the less accurate method of
carrying timeptees bodily between the various points;
and repetition and reversal of signaling enabled arrors to be eliminated from this method.

As soon as the Atlantic cable was put into success al operation its applicability for the determination of time differences between points in Europe and America became evident, and so the work has gone on, until now the methods of radio-telegraphy are being drawn

into service. While the difference in longitude between Paris and Weshington is already sufficiently well known for all practical purposes, the existhinament of a regular wire-less time service, covering the wide areas served by the Paris and the Artington stations will enable numerous stations in the West Indies, in Central America, and is South America, to be equally well served, said these, in term, will herve their various tentroless.

#### bed in side

A CONTRACTOR OF THE CONTRACTOR

Semispheres Regulate Street Traffer. Experimental touth have been made this fall in Chicago of a semaphore signal for the control of steet traffe at the crossings. The semaphore is troadly similar to those used in railroad service. It is operated by the pollowman on duty at the crossing and it can be seen fully a blook away. There should be a future for this device, especially at the intersection of the busiest main thoroughteres of

Government Protects Naval Secreta.—The United States Government has brought suit against the E. W. Bliss Company, which owns the patent for the Bliss-Leavitst torpedo in France, Japan and England. The company whisse to give the details of its system to Whitehead & Co. of England. The United States Government, instaing that it owns a proprietary interest in the torpedo, is seeking to prevent this disclosure.

Engineering Reducing Corrosion in Pipes.—It is observed that the gases which water holds in solution have a marked effect upon the wear of from and steel tubes, and if the coyrgen is eliminated, the internal corrosion of piping is lessened to as much as one tenth part in certain cases. Following this method the hot water piping used for central heating systems can be protocated and will last much longer. At the top of the hot water pipes is mounted an air separator of suitable design which serves to remove the dissolved air. This is found to be very efficient.

Substituting a Steel Rallread Bridge in Two Minutes.

A steel bridge was recently removed and Shplaced by another, new Yotor, N. Y., on the Lahigh Valley Rall-road, in the remarkably short space of under five minutes; and this was done without any delay in the traffic. The new bridge which was put in place complete, even to its ballasted tracks, is a plate-grider structure, with a span of 108 feet. The main griders are 10 feet high, and it has a solid concrete floor. This mass was rolled into place in three minutes and was ready for immediate use. The old bridge was rolled out of the way in a minute and three quarters.

Feed Water Heating.—The new Brooke high, velocity feed water heaters are claimed to deliver water 20 degrees hotter than the usual heaters, and gain a considerable saving of fuel. When working with exhaust steam it is known that heaters find a difficulty in delivering water hotter than 170 to 180 deg. Fahr, when working at maximum capacity. With the new system this can go as high as 200 deg. Fahr. Such heaters are made in vertical and horizontal types and work equally well on live and exhaust steam, a very economical arrangement being to have an exhaust and a live steam heater working in conjuncting

Steam Meter.—It is a well-known fact that a large amount of steam is wested in many plants, and as this waste occurs in ways which cannot easily be detected, it would be of value to have an efficient steam meter. This is also useful for plants which deliver steam for different purposes in a works, in order to resion the cost in each department. The new Curnon steam meter is now proving to be quite a benefit to steam users. It operates by means of a small plug inserted in the steam piping which carries bent tubes placed in the path of the steam, these being connected by small plug place for the recorder. The recorder itself can be placed at any reasonable distance from the steam piping.

reasonable distance from the steam piping.

To Recerd Aeropiane Vibrations.—The vibrations which are produced by machines can be recorded upon a drum by well-known devices; but when it comes to recording the vibrations of an seroplase framework which is in movement in the sir and thus has no fixed point of support, the matter is much more difficult. A recent apparatus made by the Due de Guiche consists of a small air chamber covered by a disphragmenthich is weighted by a heavy disk. The inertia of the metal disk server instead of a fixed point, so that the air chamber transmits the different air pressures due to vibrations, by a firstible tube, to a second disphragment chamber, provided with a metal point which makes a record on a drum. We expect to describe this device.

Gieves for X-ray Werk.—The proteoting gloves which are generally in use for X-ray work are ordinary gloves having aspited on the back a layer of lead-containing ruther, as lead is known to stop the rays. But this layer is somewhat stiff and lacks suppleases, and besides it is only the back of the hand that is protected and the palm and sides which are often exposed to the rays have no such shield from their action. A Freach inventor makes use of a fabric which is much more facible and it protects the whole of the hand from injury by the rays. The new fabric is worse from slik which is heavily "sized" with a lead composition, so that it contains three times its weight of lead. This tissue has the advantage of being much more classic than that which has been used up to the present, and sate as a very good screen for the X-rays, especially when the back portion is reinforced. It will no doubt render good service to operators, who always run the risk of severe burns.

Electrical Protection of Ships' Halls.—That the corrosion of the exterior of ships' hulls is very largely due to electrolytic action is presty extensively recognized. The joined plates, immersed in sea water, form so many battery cells owing to the obnemical dissimilarity of the plates, and in each such cell the positive plate becomes pited. It is well known that boilers, condensers and the like may be protected against electrolysis tending to destroy them by attaching plates of sine in their interiors, since by the electro-negative relation of the interiors, since by the electro-negative relation of the non of the boller or endenser to the sine the latter is corroade and the iron rendered immune from corroston. The new method of protection of the hull is to make the latter electro-negative to a specially disposed from anote set in the hull in contact with the sea water. The special anode or anodes, insulated from the hull, are connected to an electric generacy the to ther pole of which is grounded on the hull. In this way the destructive action of the sea water is directed to the anotes alone; and the merit of the idea lies in the fact that those anodes are easily and cheaply renowed when necessary.

Generator of Record Size.—While we are familiar with large alternators for use with stars untrinse of 25,000 horse-power, and there are several projects on foot for machines of as high as 40,000 horse-power, the size of continuous current generators has not followed the recent progress in designing large machines. This is due to difficulties of construction inherent in this class of dynamo, especially as regards commutation. A machine recently built in France is of 4,400-kilowart capacity, which appears to be the record for size. It was built at the extensive works of the Société Alascienas Belfort and will soon be running at the central plant of the Longwy Steel Works. The machine is a generator on the 3-wire system with 489 votte maximum, and furnishes a current of 9,170 amperes, working at a standard of 94 revolutions per minute. Of the usual multipolar type, the field has 24 poles and also a set of commutation poles. Exterior diameter of this giant machine is about 18 feet and the total weight 86 tons. The ortsating set weight 38 tons. The present generator is to be coupled direct upon a gas engine. A second machine of the same kind in one wider construction.

machine or the same kind is now under construction. Diesel Engine for Electric Generators.—The use of different kinds of prime movers for driving electric generators has also led to special designs of dynamic landers of the property of th

Karakul Sheep in Canada.—Consul Wesley Frost, stationed at Charlottolown, Prince Kdward Island, reports that a small flook of karakul sheep is to be imported into that province from Texas. Prince Edward Island has recently achieved considerable notoricly through its remarkably literative fox-breeding industry, and leading raisers of foxes are backing the new enterprise. It is proposed to cross the karakul sheep with the long-wood sheep of the island, which are eclotarised for the fine buster and strong fiber of their wool, in the expectation that a strain of hybrids will result having the tight ouris of the karakul at birth together with the gloss and strongth of the lond breeds.

The Evolution of the Rievator has not progressed to far in Europea as in this country, partly, perhaps, because the symmetry of Europea actives into the rimined with the skyeresper, so that the elevator is haddly anywhere an absolute necessity. An American consular report points out the fact that in the Old World three contraines are still regarded obietly as means of carrying passengers up, not down, an idea expressed in the names "devator." "Hit," and "seacessur," used, respectively, in America, Great Britain, and France. The commonst type of elevator met with in medium-priced hotels in France and Germany is controlled by a series of push-buttons on the outside at the bottom of the shaft. A person wishing to go to the third floor enters the ear, and an attendant who remains at the bottom for the shaft. A person wishing to go to the third floor enters the ear, and an attendant who remains at the bottom pushes button number three, the car stops at that floor, and the passenger, on leaving the ear, calls down the shaft that the ear is free. There is no corresponding provision for coming down—stairs are for that purpose.

## The Manufacture of Hydrogen Gas for Spherical Balloons

#### Portable Plants for Military Use

By the Paris Correspondent of the Scientific American

THE progress recently made in developing the spherical balloon and especially the airship for military or other uses, has caused increased attention to be paid or other uses, has caused increased attention to be paid to methods for producing hydrogen gas in large quantitles to meet the growing needs and in a sufficiently tate. Of late the extensive use of air countries as a part of the army outfit, has led to a countries as a part of the army outlin, has led to a search for suitable hydrogen-producing plants especially adapted for military use—Fixed hydrogen plants are of course useful in connection with aeronautic establishments and army centers, but what is especially valuable now is a portable outfit of this kind which can so that the airships can be supplied in the best manner By the adoption of a hydrogen plant mounted upon rati-road cars such as we represent here, it will be seen that the effective work of an airship will be at once inused, owing to the fact that it is constantly kept in good order by the available supply of gas. Wanting this, the airship would often be laid up, or at lea subject to more or less delay in carrying out its work.

A hydrogen plant of the present kind not only serves for aeronautic purposes, but the gas can be supplied from either fixed or movable plants for use in different electric welding of plates or bars, and similar work for which a considerable amount of hydrogen is needed at ent, also for cutting of plate iron by the hydrogen blowpips. The hydrogen-producing methods used mainly up to now are purely chemical, electrolytic, or regeneration processes, but all have their disadvantages supared with the present oil gas method which is ed by the inventors. In some cases the first cost or rative expenses are high, and in others the gas need

cheap electric power can be employed or in the other cases where a water gas plant can be installed to ad-vantage. In such cases the hydrogen needs to be trans-ported in steel bottles under pressure, which is an added cost. Some processes do not give a pure enough hydro-gen, one which shall be free from arsenic and chlorine, gen, one which shall be free from arsente and chlorine, and it is known that areenic has caused even mortal accidents in this way. As to chlorine, the gas for use in airships must be free from it, for chlorine attacks the balloon envelop.

According to the new German hydrogen process de-vised by Rincker and Wolter, the gas can be produced in any suitable place and the plant occupies but a small with a very cheap production. pact shape of the apparatus makes it very well adapted for mounting upon cars so as to give a portable plant for airships. In fact, it appears that the German army is much interested in the present method and expects to use it for supplying airships of its numerous fieet. The gas which is produced in this apparatus has but a small percentage of nitrogen and has a specific gravity of 0.087 to 0.092. The operation is based upon the use of crude oil to produce the gas, so that a supply is easy to have. Instead of this, the so that a supply is easy to have. producer can also be made to work upon benzine, refined oil, benzol and the like. Heating is done by the use of coke, as a general rule, although this can be replaced charcoal. In the large engraving will be seen the teral makeup of the plant mounted upon two railroad cars such as is designed for use in the field in army operations. In this apparatus the first part consists of the gas producer layout which is mounted in complete upon the front car, while the second car has

remainder of the plant, including the co remainder or the plant, including the court, Schools, and other purifying devices. This second part of the apparatus is especially needed for giving pure gas which airabips require, as otherwise it need not be as elaborate for use in other industrial processes where less pure

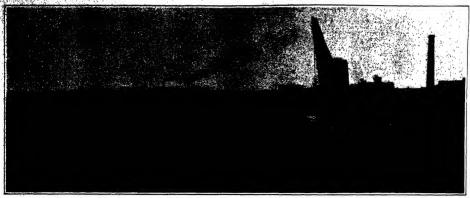

The main apparatus on the front car oor pair of gas producers. Each of these has plate iron casing which is lined with fireb remove slag and ash, there are two doors in the front which are kept closed while the gas is being p On the top of the apparatus is a hopper for use in field-ing in the coke. At the bottom of the producer are good-sized pipes which bring in the air blast from the blowing chamber. The first of the two producers also has an oil agray device for introducing the oil at the top part. The producer is filled up with coke as is coming from a steam turbine driven blast fan, this orked by the steam from the locomotive. If need be, the blast fan can also be driven by a gus or crude oil engine of the usual kind in the case of the portable plant, or with a stationary plant a gas engine, electric motor or any suitable mechanical drive

Oil for the spray is supplied by a spitable oil pump which feeds from a large tank on the car. It is nece sary to heat this oil before feeding it into the producer. the steam from the turbine is for this purpose, so that the heating is economically done. At the start of the apparatus, both producers are filled with coke and fired up. By the use of the hot air blast the coke is brought to a white heat, and

FINISHING A BATTLESHIP AT THE ELSWICK WORKS

## Some Notes on the Armstrong Works

#### A Pioneer in the Development of Modern Ships, Guns, and Armor

I N speaking of the great engineering firms of the prestent day, there are deriath names that may be termed generic. Such for instance, are those of Edison and Westinghouse in this country, Krupp in Germany, and Vickers and Armstrung in England. It is bayond the compass of this journal to give any ex-

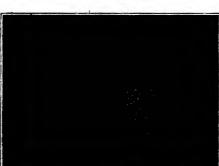

compass of this journal to give any extended description of a works which is so intimately associated with the lastnamed engineer; it is our purpose merely to give a few historical notes on the foundation and growth of the Aristroup concern, and a brief description of some of its ontput, as pictured in the accompany-

its output, as pictured in the accompanying illustrations.

To many who read these lines it will
come as a surptie to learn that Lord
Armstrong, the founder of the great works
under consideration, started in life as a
iswyer. But if he was a lawyer by profession he was an inventor by instinct
and natural endowment, and as early as,
the year 1886, his thoughts turned to the
promising possibilities of water as a motive power, and for several years he devoted his very fees mind to the study
of hydraulics. As the outcome of this, in
1846, we find him lecturing to the Literary
and Philosophical Society of Newcastle-onType, on the "Employment of a Column
of Water as Motive Power for Propelling
Machinery;" and a year later he exhibited
his hydro-electric mechine. Half a century later, locturing before the same socie-

Extended the control of the control of

ty, he spoke to his audience of the dense crowds that had collected in 1844 to see his hydro-electric apparatus, a crowd so dense that he had to enter the lecture room through a window. In 1846 the Royal Society elected him a fellow, and about the same time the first by-

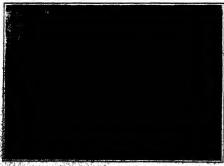

Instantaneous photograph showing the incandescent fragments of a shell which has broken up against a plate.

draulic crane was erected upon the Newcastle quay. So successful was this, that in 1847 an engineering establishment was opened upon the Tyne at Elswick. The success of the hydraulic crane was immediate and widespread; and upon the heels of this followed Armster and the succession of the succession

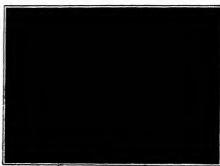

strong's invention of hydraulic mining machinery. The invention of the accumulator, which rendered it possible to employ hydraulic power where there was no natural head of water, gave a great stimulus to the new invention.

to the new invention.

The outbreak of the Crimean war brought Elewick for the direct time in touch with the British War Office. The heavy artiliery of the British Service had made practically no advance since the time of the Peninsular cumpaign and the battle of Waterloo, forty years before. Armstrong, with that distinguishing facuity of transferring his whole energy and attention to various subjects in turn, now became completely absorbed in the study of guns, carriages and projectless. In 1834, soon after the battle of lakerman, be designed and built a three-pounder built-up run which is still on exhibition as a historical relie at Elswick. It consisted of a core of steel enveloped in colled iron cylinders shrunk one above another. The gun was rifled and breech-loading and carried a movable ventpiece. In bringing this gun into general use there was the usual government anothy and inertie to over-

Pair of heavy gips on their terret turntable. Audrentic

To save room, this sarpeds tube receives its torpede from the side instead of through the breech.

come, but ultimately a committee reported in favor of the Armstrong system on every point; indeed, there was no rival system in existence. Armstrong laid before the committee an entirely new system of field artitlery, embodying in the gun a standard of accuracy and rahitherto unknown, and providing a piece that was com-

plete with carriages, projectiles and fuses.

The distinguished inventor now entered the government service with the title "Engineer of the War Department;" and he at once made a gift of his gun pat-ents to the nation. Just at this period the Elswick Ordinance Company was formed, and shortly thereafter Armstrong was knighted by the government in recog-ultion of his abilities and services.

In 1863 the British government repudiated their arrungement with the Armstrong Company and it was not until fifteen years later that the Elswick experts suc-ceeded in forcing upon the government their new type of gun, a type which with certain modifications is no adopted all over the world.

In 1869 the Ordnance Department of Elswick was started, and shortly thereafter there joined the staff of the company a certain Capt. Noble, a young artillery officer whose name was ultimately destined to become fumous as the leading expert on explosives in the world. Sir Alfred Noble is to-day head of the huge ordnance department at Elswick, and chairman of the company. Bereft of government orders, the company began to dish a foreign trade which has since grown to enormous proportions. Up to date, the Armstrongs have built for the Japanese Navy 13 ships, for the Chinese, 22; for the Brazilian, 11; for the Chilean, 2; and for the British Navy, 44 ships. The total output of the firm to date numbers 135 warships, with a total displacement of 565,029 tons and a total horse-power of

As a result of Capt. Noble's researches and experimental work, there came about a revolution of the whole science of gunnery; for by the introduction of slow-burning powder, he opened the way for the construction of an entirely new type of gun. This was completed and brought to the notice of the British government in April, 1877. Subsequently, that notable gunmaker, Whitworth, amalgamated with the Armgunnasker, whitworth, amalganated with the Arm-strong Company and a new company was formed under the title of Str W. G. Armstrong, Whitworth & Com-pany. In 1885 Armstrong opened up a branch for italian work at Poznolli on the Bay of Naples, where for twenty-six years guns and mountings have been built for the Italian army and navy Limitations of space prevent any further narrative of the development of the various branches of this firm, and it must suffic to say that in Newcastle alone, 120,000 men, women an children are dependent on the Elswick works for their

One of the largest departments of this firm is that devoted to ordnance. We present illustrations show-ing the method of mounting the large-caliber, wirewould naval guns, which are minufactured in such large numbers for the British and foreign navies. In onr own savy we use a purely electric method of control, both for training and elevating. The British have always used and still adhere to the hydrautic method, which they claim gives excellent results in speed and necuracy. A striking illustration is the one showing graph taken at the instant of impact of a 9.2 inch shell against a Krupp plate. The work done upon the plate and the projectile resulting in the generation of intense heat is very graphically shown in this picture. The particles of steel dust and fragments, highly incundescent, have been caught by the camera as they were scattered, white-hot, in all directions. The edo tube Illustrated is one of the latest pattern designed for underwater use abourd ship. In order to re the size of the torpedo room, the tube is form in two halves, one of which can be unlocked and open laterally as shown, to allow the torpedo to be inserted from the side. The tube is then closed up and locked by the manipulation of levers shown to one side of the

Warships built at the Elswick works have to pass telow a high level bridge, farther down the Tyne, on their way to the sea. Hence the peculiar appearance of the Iripod most of the ship, shown in our engraving It will be seen that the mast is broken at the level of th smokestack, the top half of it being carried temporarily upon scaffolding, and subsequently riveted in position.

#### The Use of Cocoa Shells as Fodder for Cattle

A 18E has been found for the cocca shells which are A is product of the chocolate industry in France as fodder for cuttle. The cows like it and it is nourisdiscipled to the constant of the core USE has been found for the cocoa shells which are ing and fattening, having much the character as wheat ing and fattening, having much the character as weath-bran, but it is thought by some authorities to iessen the milk yield, though not lowering (but even increasing) lis fatty content. A report on the subject has been made by an agroundic equipeer named Lucas to the National Society of Agricofiture of France. The ques-

tion is to be further studied and is of importance, as this product consists of no less than three to five mil mes yearly, according to Les Annales

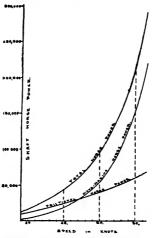

#### The Problem of High Speed in Ships

NOT many people understand why, in the higher branges of speed, it is so difficult to add another knot or two to the speed of a fast ship. To the naval architects of course, the problem is a simple one. Not so to the layman, who, generally speaking, cannot un-derstand why such a great increase must be made in the horse-power to gain the last knot or two. One of the most lucid explanations, of a popular character, of this problem is contained in the last issue of the Skipping World, in the form of an article contributed by a member of the Institute of Navai Architects of Great

a member of the Institute of Naval Architects of Great Hritain. We republish the diagram accompanying that article, and the following is a digest of the paper. The writer (M. I. N. A.) of this article was prompted to take up his yes by observing the ridiculous press statements as to the speed of the "Queen Mary", the latest of the British battle-cruisers, when she was on her trial. Nhe was designed for 28 knots, and it was alleged in the press that she attained a speed of 85.7 knots and was expected to do better when the crew ecame more familiar with the ship.

In order to indicate what expenditure of power is

involved in increasing the speed of a vessel, the accompanying diagram was prepared, showing the horse power necessary to drive a ship of the dimensions of

The shaft horse-power of a battle-cruiser at vary-

the "Queen Mary," 660 feet long, with a displacement of 27,000 tons, at speeds intermediate varying between 19 and 36 knots. At the designed speed of 28 knots the total shuft horse-power to be developed is 70,000. In order to reach the speed she has been credited with, 35.7 knots, the shaft horse-power necessary would be about 244,000, that is, about 3½ times the power that she was designed to develop under ordinary circum stances. That the unchinery could never develop any-thing like this, needs no demonstration. The diagram shows that at 28 knots the horse-power is 70,000; at 29 knots, 81,000—an increase of 15.7, per cent. At 35 knots, \$3,609—an increase of 15.7, per cent. At 35 knots the horse-power is 213,000, at 38 knots 225,000, or an increase for this advance of 21.1 per cent. We can thus see, that, at the lowest speed, 11,000 horse-power is required to increase the speed by one knot, and at the highest appear of \$5.00 knots, and at the highest appear of \$5.00 knots, and at that a by no means an extraordinary case; for in that this is by no means an extraordinary case; for in the case of some ships it would take double the power is transmitted. to increase the speed by one knot. It is possible that the "Queen Mary," with a designed horse-power of 70,000, has reached 29 knots and a trifle beyond, but that in itself is an exceedingly good performance.

The resistance to motion of a side, through the water

The resistance to motion of a supplicitioning the water consists practically of two parts—the frictional resistance due to the rubbing of the water against the underwater part of the ship, and the resistance caused by wave-formation. At the higher speeds, large waves are formed-that is to say, heavy man

mounly being lifted above their normal level; and continuously being introd above tours specially activities, as anyone can understand, requires a consistent into large expenditure of energy. At low speed, rictional borse-power is greater; at above 27%, for the frictional and wave-malding borse-power are sequenced. After that the frictional horse-power increases a liftle faster than the speed, and the horse-power necessary to roll up the ever-increasing waves formed by the ship's progress rises at an

#### Is the Panama Canal Liable to Damage by Earthquakes?

By Charles Davison, Sc.D., F.G.S.

THE recent occurrence of three rather severe earth quakes and of many others of less intensity in Panama has naturally drawn attention to the possible effects of still stronger shocks upon the canal. generally held, I believe, that the danger is so It is that it may be disregarded. It is pointed out that the region is one in which earthquakes have in the past region is one in which entroquases have in the past been rare and almost innocuous. And, to this, it is added that, owing to its geological structure, slight-tremors, if anything, rather than destructive shocks, may be expected to occur in the lathmian district. For both reasons, there is much to be said, but neither seems to me quite conclusive. It does not follow that

a country in which strong earthquakes have been infra country in which strong earthquases have been inter-quent or altogether absent for several centuries will remain immune for yet another century, though it is vory probable that the present condition of stagnancy will endure indefinitely. But instances to the contrary are not unknown. The strong earthquake of 1884, which caused so much damage at Colchester (England) and the neighboring villages, occurred in a district in which no recorded earthquake has ever originated and in which none but slight shocks have been felt. State of South Carolina was by no means celebrated for strong earthquakes when Charleston was partially destroyed in 1886. Nor was Alaska known as a distincseismic district until 1899, or perhaps until 1995, when the evidences of the greatest record d earthquake uplift were revealed to Messrs. Tarr and Martin.

Again, too much stress should not be laid on the

rarity or absence of actively-moving faults in the Isthmian zone, for surveys in mining districts show that faults may exist at the depth of the mines which a survey confined to the surface would not have detect-ed. Nor is this all, for, as in the Swanses earthquake of 1906, the seismic cridence may indicate the exist-ence of still more deeply-scated faults, which the most detailed observations either on the surface or in mines would never have revealed.

But, though it is not impossible that destructive ocks may occur in the immediate neighborhood of the canal, it seems on the whole probable that the prospect of any damage resulting to the works is but a small one. It should be remembered that the epicenter small ones. It should be remembered that the epicenter of the recent earthquakes was at a great distance from the Isthmian zone. It is true that, on October 1st, a few walls were cracked in Panama City, but the chief damage occurred in the provinces of Los Santos, and expecially at Touosi. As most of the after-abotics were felt in the same district, it is probable that the epicenter of the earthquakes was not far distant. If we take it to have been about a hundred miles from the canal, it follows that, to cause serious injury to the workings, the meizosetsmal zone would have to attain the considerable area of about 30,000 square Unless, thorefore, there should be a marked oce of the epicentral sone toward the canal, it would seem that little danger is to be apprehended earthquakes originating in the Los Santos center.

But, even if a violent earthquake were to occur at some place much nearer the canal, it does not follow that the works would be seriously injured. Twenty-five years ago some interesting observations were made by Messrs. Sekiya and Omori at Tokyo. Two similar setsmeasure, sestiva and omore at 1000. Two similar seits-mographs, which had previously been compared on a shaking table, were placed, one at the hottom of a pit 18 feet deep, the other-on the surface close to the pit. The records given of the earthquakes of two years (1887-1889) were afterward compared. If the earth-quakes were slight, it was found that the records on the surface and in the pit were nearly the same. But. if the earthquakes were strong, the differen once noticeable, not so much in the large undulations as in the small tremors or rippies superposed on them. as in the small tremors or rippies superposed on them.

In the pit, the rippies were to a great extent smoothed away. If the intensity of an earthquake short depended only on the range of the motion, this would not be of much consequence. But it depends also on the irrevity of the period of the vibrations, and, on this account, the ripples possess an intensity several times got than the large undulations. The effect of smoot away the ripples is thus to reduce the actual inte of strong earthquakes, so that at the bottom of the may be only about one fifth of that at the surface."

#### The Double Report of Gun Fire

To the Editor of the SCIENTIFIC AMERICAN; In an article you published some time ago on a visit to the Atlantic fleet during target practice, the writer to the attention need during target practice, the writer speaks of hearing a double report when a shell from one of the small guns passed near their ship. He states that one of these reports came from the gun, but the the officers of the fleet were not sure as to the cause of the other.

I mentioned this recently to a friend who has seen active service in the Philippines, and he said that he had often noticed a sharp report when a steel-jacketed bullet passed overhead, and that when the bullet passed that of the rifle. This noise is not noticeable in the low-velocity lead builet.

I mention this is case there are any of your readers who are interested in this subject.

Baltimore, Md.

AUGUST MENCKEN.

#### Automatic Sprinklers at See

To the Editor of the SCIENTIFIC AMERICAN: In your editorial on "The Peril of Fire at Sea, is your entorial on "the PPFII of FIFE at Sea," In issue of October 25th, 1918, the question is asked, "Why is it that the automatic sprinkler, which has proved so highly efficient ashore, has not been applied to the tection of ships?

I beg to inform you that automatic sprinklers have been installed in a number of steam vessels plying the Great Lakes and Long Island Sound. I have before stographs of two lake steamers that are partially protected by sprinklers. As you say, "structurally con-sidered, the problem should not be a difficult one." And the problem of water supply is easily solved by the provision of automatic Underwriter fire pumps, or air-pressure tanks, maintaining constant pressure of water on the sprinkler system at all times; and where there is danger of freesing, the installation of a dry-pipe system will obviate that difficulty, as is the practice

Now, Mr. Editor, the answer to your question is, that sprinkiers are not installed generally in ships for the same reason that they are not installed in all factories. The owners will not pay for them; it is so much easie. to "take a cha P. D. C. STEWARD. Philadelphia, Pa.

#### The Busiest Railroad Terminal

The Busicet Railroad Terminal
To the Editor of the Scurwirzo Auguston;
A paragraph in Engineering Notes in the October 18th
number, gives the impression that the busicet railroad
terminal in America is the South Station at Boston,
rit will probably surprise most of your readers to
learn that the "Busice Terminal in America" is not in
Boston, spe in New York, nor yet in Chicago, but is in
fact on the other side of the southest entirely.
The busiless of the Union Ferry Lepoch at San Francisco surprises, oven that of the South Station at Bostops, by over; a million and a half a year.
San Francisco is so situated that nearly all pessuggest sculing; the city are compelled to do so over

conners reaching the city are compelled to do so over

alor of the

the ferry lines of the various railroads, all landing at the Union Ferry Depot.

For the fiscal year ending June 80th, 1913, the official figures give a total number of passengers handled

as 89,955,578 distributed as follows: San Francisco-Oskiand Terminal Hantways
Western Pacific Railway
Santa Fé
Northwestern Pacific 89,362 299,987 488,989

Monticello Steamship Company ..... Oakland, Cal.

#### Spreading and Overturning of Rails

To the Editor of the SCIENTIFIC AMERICAN:

I write this for information concerning "spreading rails." Do rails spread and cause wrecks on railroads or do they turn over?

I think there is a difference between rails spreading and rails turning over.

and rails spread the rails would be pushed out at base of rails and spikes would be pushed out from rail on outside or else their heads would be sheared off.

If rails turned over then the spikes are pulled on the inside of rails.

In my opinion we would not hear of rail spreif angle bars at rail joints did not get loses and allow pounding at joint, with the result that the wheels push the rail over at joint and turn the whole rail over. This is the option of a man that was for thirty-five years a trackman on a first-class railroad, and had as

uch experience with wrecks as almost any man, and I think he was right.

Will some one better informed entighten us on the ZACH T. HOSKINS. subject?

Chicago, Itt.

Cour correspondent is correct in his explanation of the action of the rail on the spikes in the respective cases of turning over and spreading. Low joints, in our opinion, are only one cause tending to produce reading and overturning by setting up oscillations of the engine and cars.-Entre

#### The Use of Oil at Sea

To the Editor of the SCIENTIFIC AMERICAN:
Not enough attention has been paid to the use of oil
in the reacne of the "Voiturno's" passengers.
The great increase in the number of lifeboats since

the "Titanic" disaster is shown not to have solved the problem. Even with the most improved davits, boats pronem. Even with the most improved dayits, boats cannot be launched in a high sea. From a height like that of the decks of the "Olympic" or "Imperator," the boat and passengers will be lowered to certain destruc-

The use of oil has often been shown in such cases. Every tug with barges in tow should be compelled to take a supply. Seven lives were lost off Cape Cod inst week, following hundreds of others. If oil were used e tugs could take the men off the barges in any weather; whereas now they are compelled to let them drift to destruction.

Life savers along the coast could throw oil, in rockets or projectiles, to windward of a stranded vessel, and greatly increase the chances of saving the crew. Patent Office records are full of such devices, and no doubt the simplest would be found the most effectual.

The Ordnance Department of the Army would be well imployed in co-operating with the Life Saving Service in perfecting such a projectile. The Revenue Service could use oil freely in the many rescues they are called on to make. The device is an old one, but its use should be modernized and made effective, and no ship should be allowed to sail without proper equipment for the use of oil, for the safety of its own passengers, or saving the lives of others, found in danger.

New York city. TOURSE D. HOLMES

#### To Our Subscribers

W.E are at the close of another year—the sixty-ninth of the SCHENTIFIO AMERICAN'S life. Since the subscription of many a subscriber expires, it will not be amise to call attention to the fact that the sending of the paper will be discontinued if the sub-acription be not renewed. In order to avoid any in-terruption in the receipt of the paper, subscriptions should be renewed before the publication of the first of the new year.

#### The American-French Radio Time Signal Experiments.

THE Naval Observatory succeeds in receiving time signals from the Observatory of Paris by radio telegraphy via the Eiffel Tower and Arlington, for longitude determination.

For about a month the Naval Observatory at Washington and the Observatory of Paris have been sending time signals to each other, using the Arlington radio station and the Elffel Tower in a campaign to determine nce of longitude between the two pla the velocity of propagation of radio signals through Owing to interference from other radio stations, but principally to discharges of atmospheric electricity, there has not been much success until the night of November 19th, when the beats of the Paris clock as transmitted by radio signals were compared with the Washington clock for some minutes by the method of coincidences. The season of the year when atmo-spheric conditions are best for radio work is now coming on, and it is expected that the work in which the can and French commissions are engaged will proceed as planued.

e Naval Observatory was the first institution in the world to have its time signals regularly transmitted by radio telegraphy for the benefit of ships at sea, enabling them to check their chronometers and thereby better determine their longitude, and it also has sent signals in this way to enable surveying parties under the Hydrographic Office to determine the longitude of points which they used as bases.

Although radio signals travel through space at approximately the velocity of light, there is a slight but appreciable loss of time (a small fraction of a second) in starting such a signal on its journey away from the serial of the sending station and in receiving it at the other end. It was desirable to eliminate this loss of accurately measure it, and the observatory was considaccurately measure it, and the observatory was considering this problem in 1912, when it was ascertained that the French had already solved it by one of the methods which were suggested for study, viz., that of "coincidences." Here was a beautiful solution and the superintendent of the Naval Observatory, realizing its possibilities, proposed that steps be taken to arrange with the French government to exchange signals been the Eiffel Tower and Arlington

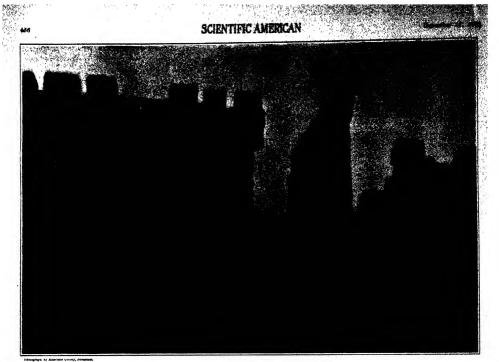

The Navy Department would have been content if granted simply the privilege of taking its own astro-nomical observations in Paris and using the Elffel Tower radio station for sending signals, but the French gov-ernment showed the keenest interest in the problem, and last spring sent five of its leading experts to this country to study il, while the Navy Department had representatives in Paris for the same purpose As a result of these preliminary investigations it was agreed that there would be an American and a French commission which would work side by side, but independently, cach commission having a party in Paris and another in Washington at the same time, until one balf of the observations and exchanges of signals were completed, when these partles would exchange stations, taking their instruments with them, and repeat the process.

The interval since last April has been devoted to get ting ready. Two special telescopes have been provided for the American parties, which are designed to elim-inate as far as possible instrumental and personal errors, and the exchange of stations is intended to still further eliminate such errors from the final results. Two instrument houses have been built, side by side, at the observatory, identical in design, one to house the French and the other the American party. These houses are considered models of their kind and will be available for future use in similar work.

Four radio experts were ordered from the fleet to the Naval Observatory to get the necessary experience to enable them to compare the clocks, separated as they are by about 3,800 miles, and to assist in making preparations. Two officers who had had experience in hydrographic surveying were also detailed to join the astro-nomical staff of the longitude campaign. A great many details had to be studied and tested at the observatory in preparation for this great undertaking, as the apparatus in Washington and Paris differ considerably.

The same signals which are set by the Arilington

radio station for the Naval Observatory are to be used by naval hydrographic surveying parties in the West Indies and Central America, and fifteen observatories scattered from Maine to California have already indicated their desire to take advantage of them to deter-In this way the undertaking inaugurated by the Naval Observatory will have a far-reaching scientific and practical influence, and that observatory already is considering a still more fur-reaching underlaking, namely, that of tyling together the continents of North and South America and many of the Islands of the Atlantic and Pacific, and possibly some of the countries in western Europe, by longitude determinationbased on radio signals to be sent from the radio station to be built by the Navy on the l'anama Canal Zone

The cyclopean wall and lofty pillars of the Great Temple, Baalbek.

## Baalbek the Mysterious

#### In Many Respects the Most Famous Ruins of Bible Lands

By Harold J. Shepstone

A MONG the grandest relies of a great nation's vanished giory stands the ruins of Bauliek, certainly one of the most mysterious of ancient cities. These ruins in Kyria are rightly renowned for their massiveness and for the great mount of both bold and delicate carvings with which they are adorned. An account of them is appropriate, for through the German excavators, under Dr. Sabelsinian and Prof. Puchsielan, who have been tolling here for four years now, much new and interesting light has been thrown upon the history of this once famous city. Indeed, these savants may be said to inve done for Bauliek what Layard did for Mineveh and Babylon and Schielmann for auceint Troy. Still it must be admitted that the work of the Germans has not been altogether a dishietered on, for the Berlin museums now possess unny of the finest examples of carvings found here.

These wonderful rains, he some respects the most frames in Bible lands, the in the narrow pleturesque valley of the Linuin short distance west of the Bible lands, the in the narrow pleturesque valley of the Linuin short distance west of the Bible lower of Bundlack, at an attitude of some 4,000 feet alrews see level. The town is about ten unless north of the railway which runs from hefurt to Damascus. To visit the ruins, therefore, one goes by train from Eleptra to El-Mundiaka, from which place they can be reached in an hour or two by carriage. Here the ancient Agayrians wondinged Band, the Greeks Hellos, the Got of the Sun, and the Rumans Junjee. The early Christians, to, worshipped the Gol of Jedovach at ancient Bandlock, turning the great pagan temple into a thristian sharine. They, in turn, were driven out by the Arabe who converted these wonderful old temples toto forteresse.

Although Inscriptions and tablets found make this very char, we have, nevertheless, very little knowledge of ancient Basiles. Its history is lost in the thick obscurity of a very remote past, and even its existence was for centurel utterly unknown. The extraordinary silence of the ancient Greek and Roman writers concerning a plane so accerancy avoidintly, important, and magnificent is supercontable. John of Anticol is the

only medent author by whom it is mentioned. And he was wrong In many of his statements. He ascribed these ratios to Alins Antoninus Pius, decisting that he built the great (cuaise at Heliopolis, near Libonous, in Phoenicia, which was one of the wonders of the world in the early days of the second century. Inscriptions found by the German excavators would go to show, however, that the great temples were begun by the Homania in the first century after Christ, and this view is also confirmed by the Nyrian writer Michel Alonf, who is a native of Basileic, and who has devoted an immense amount of time to the patient study of all

documents bearing upon the blatory of his birthplace. Virtuals written speak of Rashbek at the period of the first Arab lavasion, describing it as being then one of the most spiteadd of Nyrian cities, having stately paience adorned with monuments of great antiquity, abounding with fountains and article adornments of wonderful richmess, variety, and beauty. It ecommercial importance is shown by the fact that during its siege by the Mosiema, shartly after the fall of Damascus, the citemies captured a caravan bearing four hundred loads of silk, sugar, and other commodities; and its wealth is ascertained by the ransom that was executed, of two thousand ounces of golf, our thousand ounces of silver, two thousand ounces of silver, two thousand ounces of silver, two thousand ounces of silver thousand silk wests and a thousand sworth, in addition to the arms borne by its defenders.

Most visitors to Itanibek find the ruins confusing and somewhat hewildering Indeed, seen at a distance that are a little dissipointing, but once you stand among them and survey the messive columns, matche doors of predictions dimensions, windows and niches bordered with exquisite sculpture and fragments of besutiful niches, cornices, capitals and entablatures, you are amazed and mystified ul it all. Yet all these ruins only represent the romains of two grand temples and a smaller one—the Great Temple, or Temple of Jupiter, the Temple of Bacchus and a small circular Temple to Vonus. Nevertheless, in the colossal walls of this anietest Nyrian acropolis one could place many of the ruins of ancient Rome. The architecture of four, it

not five ages, is represented—Phoenician, Greek, Roman, Christian, and Sarucenic, while some authorities consider that there are distinct traces of Solomonic architecture.

arentecture

The rulns stand on an artificial oblong plateau of masonry, probably of Phoenician origin, about 331 ayards long by 200 broad, and varying in height from 15 to 30 feet. The enormous extent of this vast enceints may be better realized when it is remembered that the main courtyard, which serves as the approach to the Great Temple, is nearly 150 yards long and some 120 yards wide, dimensions only surpassed by those of the Great Temple at Karnak, in Upper Engyt, Beneath this colossal platform are vaulted passages like tunnels, and it was from these passages until somewhat recently that the temple area was reached.

First and foregood among these rulns therefore comes

First and foremost among these ruins therefore comes the Great Cresple. Its main entrance was from the east. Hore a wide flight of steps led up to the propries, ninetees feet above the gardens and orderade that now surround the ruins. This portice was opened to the east the full width? of the water said the worshippers used to ester between rows of columns on the bases of three of with are inscriptions stating that the temple was erected to the "Great Gode" of Hollopolia. When the Arabs compared the city they converted these temples into fortresses, and to this end to a certain create irmodeled them. The columns mentioned were removed, the statrense taken away, and the statrense would be the continue that the columns had been. The German excerntors have form away the wall constructed over: the bases of this columns had been. The German excerntors have form away the base of the columns of the columns had been and the columns of the columns had been. The German excerntors have form away the bos. The German excerntors have for the columns had been. The German excerntors have form away to be so that today one enters again as giffel the Rosan worshipers of old. Indeed, every vigities; to the critical plan more selfy comprehensible. Those of deficies have been removed and weak jearls in the ruins have been strengthened.

From the Propylets one passes to the hexagonial fore-

seems of the second to the seems of the second of the seco

In the center of the court, rather nearer to the stope seconding to the temple beyond, stands what is left of the large aitar. On each side of it is a pool or beath used for ablution in connection with the religious rites here observed. It was only during the recent excursions that the aitar ing the recent excursions that the aitar

was discovered and also the stops by which the priests ascended at the time of secrifice. When these temple were taken possession of by the early Christians a church was exected over this altar, part of which was church was exected over this altar, part of which was church was exected over this altar, part of which was church the cherrch floor was above the top of the altar. The lower part of the staircase was also filled over while the upper part was removed to accommodate to the appear. The Great Temple beyond was demoliabled to turnish materials for the construction of this church. The idea of these early Christians was to obliterate heathenism by placing this Christian byttse right in the center of this resourced temple of the heathen gods. As it seemed to work in best, the apses were placed as above described on the west with the surtance from east. Later this was considered unothedox and as

agas or agass were built at the west end so that now faces; of them agaser at both extremities of the ruin. From the spectous cept of the altar one passes by means of a wide flight of steps into the Great Temple itself. All that is now left of it, however, are six columns which formed part of the perityle still standing is still capped with Corinthian capitlas and joined by an ornate and massive entablature. They are perhaps the crowning feature of Bashok, and ptercing the sky-

Block of ceiling in peristyle of Temple of Bacchus, Baalbek.

line as they do are seen long before the rulns are seached. Prof. Taylor says of them: "I know of nothing so besquitful in all remains of ancient art as these six columns..., Prom severy position, and with all lights of day or night, they are equally perfect." From A little distance their perfect proportions make them appear smaller than they actually are. A wall 40 feet high forms a fit pedestal for these magnificent columns. They are 7% feet in disaster and with their bases and Corinthian capitals tower 70 feet into the sir, the whole being crowned by a graceful existalure some 15 feet in height. Each shaft consists of three separate places of some held together with Iron. The Turks have barbarously made incisions in the columns at several places to order to remove the from crawnal

eral places in order to remove the iron cramps.

Now the ponderous stones which form the colorest

cornice were raised in position and places at gizantic but graceful columns is a provided engineers as much as savants and quarians. The most plausible solution suggested that a sloping embankment of earth was built from the quarry a quarier of a mile distant to the top of the perityle, and the stone drawn on rollers by thousands of slaves, the method resorted to by the ancient Expytians when they built the great Pyramids. The

numerous mounds of earth still to be seen in the great court piled against the wall give some color to this theory.

So much for Baalbek's first and most famous ruin. We now come to the second. the Temple of Bacchus, which ites to the south of the Great Temple, entirely indeent of it and on a much lower level. It had no court, but was entered by a flight of steps from the east. The walls of the cella, which is oblong, are quite pisin on the outside and are built of carefully dressed stone, the joints so perfect that a knife blade cannot enter between. Around this at a distance of ten feet, on the two sides and ends, runs a row of smooth columns which form the Peristyle. These, including their capitals, are about 52 feet high and are surmounted by a magnificent entablature and connected with the walls of the cella by enormous slabs of stone which are chiborately carved with the heads of emperors, deltie interwoven with floral designs, forming ost unique celling. While the wails of the cells are still perfect, more than half of the columns forming the peristyle have failen, the north side being the best erved. Here in a niche may be seen a tablet commemorating the visit of the German Emperor to these rules in 1898.

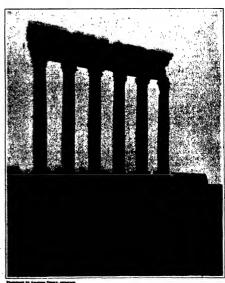

Nowthits anding the profuse or namentation of the peristyle it is exceeded by that of the portal to this temple, which is indeed the gem of the entire edifice. The door posts are elegantly carved with figures of Bacchus, frawa, cupida, sutrys and bacchantes, woven around which are grape vines and clusters of ruit, also popples and ears of wheat, all of which are symbolical of the reveiling which the temple suggested. This great doorway stands 35 feet high and 21½ feet wide, within the curving of the posts just mentioned covers a space about air feet wide. On both addes of this door stand graceful fluted columns forming the provide or profuce, while the plain ones of the peristyle, which stand behind them, seem to reflect their beauty. As a furgast years of those two incubes attended to the peristyle, which stand behind them, seem to reflect their beauty. As a furgast years of those two incubes attended.

A Particular Control of the Control

Lofty pillars of the Great Temple, Basibek.

#### An Apparatus for Automatic Transmiss and Reception of Wireless Messages By Lucien Fournier

THE apparatus described below is based on the prin-lepis of the phonograph. It comprises, in the first place, a cylinder of wax on which a sapphire-pointed tool inscribes Morse telegraphic symbols, giving the proper length to each letter and to each space bet letters or words. To the record thus pro-duced is applied a needle, which follows

duced is applied a needle, which rollows the trace made by the graver. The re-producing needle is connected by a lever to a key which operates a wireless transmitter

The dispatch thus automatically iaunch ed into space is received by means of a similar apparatus, connected with the re lay of the receiving station. The currents of this relay, by traversing the coils of an electromagnet, operate the graver, which records the message upon a second wax cylinder.

In either case the cylinder is turned by a small electric motor placed in the base of the apparatus. The axis of the cylinder is connected by a belt to the motor and by gearing to a horisontal shaft, which mova sliding bridge or carriage by means of a comb and a helicoidal screw. The bridge can be brought back to its initial position

by pressing a lever.

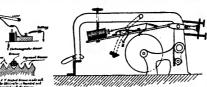

The sliding bridge carries a platform upon which the graving, reproducing and obliterating tools are mounted. The graver is attached to a bent lever pivoted to the The free end of this lever is connected by a silk cord to the armature of an electromagnet. When a current traa the electromagnet the armsture is attracted and, by the intermediation of the cord and lever, the sapphire point is forced into the wax cylinder. When the current ceases the graver and the armature are brought back to their original positions

The reproducing needle acts in a different manner. In order to bring it into contact with the grooves of the cylinder, the platform must be adjusted by means of two elevating and lowering screws is adjustment has been correctly made, the point the needle enters the groove and follows every indentation made by the graver. The needle is attached to the short arm of a lever, pivoted to the platform, and its movements are transmitted, in amplified form, to the curved end of the long arm of the lever, which, by pressing on a fixed metallic contact piece, automatically performs the functions of a morse act, and breaks the current of the wireless transmitting apparent to manned by a spring. The Perfect contact is assured by a spring.

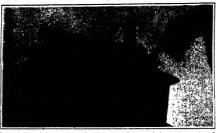

message recorded on the cylinder, therefore, is trans mitted automatically and with perfect accuracy

The sliding bridge also carries a third tool, called an obliterator, which is brought into contact with wax cylinder in order to efface the record of the

We have said that the cylinder is turned by an electric motor, but this is done only in the automatic transmission and reception of messages. In making the original record of the message to be transmitted the cylinder and the graver are operated manually by means of a special mechanism, placed in the base of the apparatus. This mechanism has three levers or keys. The middle key acts on the cylinder only and has no electrical connections. By pressing it turned by means of a wheel and ratchet, through the space between consecu-tive letters or words. Each of the other keys is simiof the other keys is simi-iarly connected with the cylinder by a wheel and ratchet, and also carries a flat spring, the end of which supports the end of a simia galvanic battery. When the key is degreemed the apring attached to it, which is will in contact with the battery spring, airlies the top of a vertical metal of which is surrounded and supported by a spiral rou when is surrounced not supported by a source spring, and is connected with the electromagnet of the graving tool. Thus the electromagnet is energised and the supplire point is pressed into the wax. At the same time the cylinder is turned through a shorter or longer are, according to the key used, so that a dot or

Diagrammatic view of the apparatus, as sending key.

General view of the apparatus for the automatic transmission and reception of

a dash is recorded. The travel of the key lever is rather long, but the duration of the current is limited by a stop which arrests the descent of the battery spring and breaks its contact with the spring a to the lever, while the key is still descending and turning the cylinder by means of the wheel and ratchet. This short currentless interval affords the graving tool time to remove itself and its shavings from the groove. The action of the dash key is identical with that of the dot key, except that the former pro-duces a longer current and turns the cylinder through a greater arc.

A new twin-propellered hydro-acroplane.

it gives the form of then if

said that the app

ages which from any trans For this purpose it is only to interculate the electromagnet by means of a suitable commuta circuit of the relay of an ordi ing station. The currents produ relay, traversing the electromagn the graver to operate in condi with those in which the original rec ord was made, except that the cylinder is turned with uniform speed by its electric motor. As the signals are being received and registered, they may be heard by means of a "busser" inserted in the dir-cuit of the electromagnetic graver. A wireless message can thus be heard as distinctly as an ordinary telegraphic mes-AR EG

In this last application the motor that drives the cylinder is started by the first call of the sending station, but, in order to eliminate the action of stray waves, the circuit of the electric motor is br by a clockwork if the call is not repeated within a certain length of time.

This apparatus, the invention of M. Leon Champeix, is capable of rendering important service in wireless telegraphy, by mak-ing possible a very accurate transmission and the repetition of a dispatch that has not been satisfactorily received. In receiving, the advantages of the apparatus are still greater, as the received and registered measure can be read at leisure by turning cylinder with any desired spe ity-now of freque obviating the neces

occurrence—of compelling the sending station to repeat the message several times.

#### A New American Flying Boat

DURING the past summer Mr. Orville Wright has Deen experimenting with a new hydro-aeroplane of the flying boat type, and he has recently brought out a machine which will undoubtedly find favor with all sportsmen interested in aviation

portunen interested in aviation.

The first Wright hydro-seroplane, it will be rememreed, was of the twin float type, and was built for

if. Russel A. Atger and flown for him by Aviator

application of the series of the seri

is not in a tight place in case the machine dives into the water, and also because he believes it to be more seaworthy. After experi-menting with this type for some time, however, Mr. Wright, aided by Grover C. Loening, the author of "Monoplanes and Biplanes" and the present superin-tendent of the Wright factory, has evolved the new flying beat shown in the ac-

companying illustrations.

The new Wright fiying boat is different in several respects from the Curtiss and from those which are copies of it. A small Wright biplane is mounted low down on top of a hy-droplane hull and contains the motor on its lower plane much as in the ordi-nary land machine. Insary land machine. In-stead of having a long up-wardly electing, topered stern or tests, that a butto-strick has a single per-sions to the middle, tapers shows to the middle, tapers there to the safe shoul last ware successful to the rand-ders of the a or opian a. ## Catalepsy in Insects

#### Experiments Showing How Insects Pass Periodically into a Trance

By Percy Collins

Extent experiments with a spectos of Phasmath, and conditions by Fatar Schmidt, Petvat Dosent of the Imparial University of St. Petratuburgh, have brought to Right the ascendiding fact that these insects pass periodicily fatio a scate of databapty or transc. The spectos in question (Gerdessels sucrosse) is a native of Northern India and Aghandrau, but for none years past it has been beed extensively in the ishoratories of Europa. St secretarily provide, and is this well adapted for Europeas of experiment. In common with most other Phasmathe, its forms is slender and stem-like, according is a requestrable manner with the twigs and branches of the piratus upon the leaves of which it feeds. Its fabilits are almost exclusively nocturnal. During the dayling it rests motionless in a characteristic attitude—the fore legs being brought close together and extended in a line with the body. In this pase its sticklife form and green color combine to vost it with a most perfect conocaling resemblance to its surround-

In the past, the long hours which this and certain other insects pass without evincing the slightest sign of animation have been regarded as periods of normal without disturbing their death-like signaber. Schmidt points out that these results are entirely in accord with what we know of catalegitic phenomena in general, vis., that the subject does not feel pain, and that the nuncies are not susceptible of fatigus. Et a lace emphasizes the fact that the catalegitic state in Phasmida arrises insturally, and from unknown inner causes. When in an sorive condition, the insects cannot be hypnotized artificially, as can be done with rabbits, crayfash, etc. For this reason he calls the phenomenon "autocatalegsy." He adds that from a biological standpoint the catalegts attee may be regarded as an accommodation to a highly developed protective resemblance. The insect becomes in no small degree a part of its environment, and completely subject to external factors. It is, for example, awayed by the wind, just as if it were really one of the stems smong which it rests.

In order to awaken these Phasmids from their hypnotic slumber, prolonged excitation of the nervous system is needed. This may be effected mechanically by phothing the extremity of the abdomen with forceps, or by electric shocks from an induction coil. It is noticeable, however, that the stimulus must be very strong with Huntington's Chorea. There were also 10,000 trait surrame eartle in the files. These embled the students of find all the data in the effice on a given trait, classed filed according to surrames (the matten names of martied women are always used when available). There are now 8,650 trait-locality cards. These combio one to locate resultly all the data in the files of the office on mechanical gentluses in Counsecticat, or any town or city in that State, or on feeth-embledness, in Rockland County, New York, and so on There are also 8,650 locality-trait cards, which collection performs, as its name indicates, the function of tracing the bistory of trails possessed by the families of a given locality is a sort of inventory of the blood of the community. Then there are the surrame locality cards, and the locality-surrame cards both numbering 8,150. The first constitutes a directory of the geographical distribution of a given family and the second serves as a directory of family and serves as a directory of the serves as a directory of family and serves as a directory of the serves as a directory of family and serves as a directory of the serves as a directory of family and serves as a directory of the serves as a directory of

On January 22nd, 1913, there were on file in the Eugenics Record Office seventy-seven requests in which intelligent persons asked for instructions for multip study of the eugenical fitness of a contemplated mar-

#### Catalepsy in insects.

siumber, or as due to instinctive promptings calculated to enhance the protective value of the creature's physical endowments—such as its abane and coloration. But Schmidt has demonstrated that the quiescent condition—at least in the case of Corression—its continue or cataleps. All his experiments have shown that the muscles of the insect are in that state which physiologists term foreibilities corne, i. e., war-like flexibility. They are strained, but not extremely so, and if they are further stretched, they remain in the new position. Exactly the same state of the muscles is observed in the case of catalepsy or "hypnosis" in the higher animals and in manifed.

mais, and in mention.

Schmidt found that he was able to arrange the Phesmids, when in a cataloptic state, in uncousts and abuormal poses, and that they would subsequently remain aboutely motionless for long periods of time. For example, he placed some on their bends, and they remained thus for as long as four and a half bourn. Others were polesd bridge-wise between two books, the middle area of the body being weighted by usens of paper align to such an actaot that the whole fasset became how-shaped. Even more remethable was the positive bow-shaped. Even more remethable was the positive bow may be a such as a subsection of the subsection which Schmidt designates the "westling bridge." This, as well as numerous other strange attitudes were ngaintained by the Phasmids for one or more heurs; nor was it possible to delsect the slightest sign of facilities or even of vitellity. Finality, some of the fassets were applicated to the ordered of mutilation; and its was found that they less, attenue and heads naight be out off, and their heddes silved into frequents.

or long continued to be effective. In normal circumstances the insects regain animation at the hour of twilight, probably as the result of stimuli connected with the processes of nutrition, though of this nothing is certainly known.

In conclusion it remains to be said that the remarkable results which have attended Schmidt's experiments should induce many students to underlate, similar investigations. If one species of Phasmid is subject to catalogic settures, then in all probability other species will be found to exhibit like phenomena. Moreover, it may well be found that the protracted periodically sustain are really flustrances of catalogys. This may be the case, for example, with the strangs, attick-like caterylliars of the geometrid moths whose babtic resemble so closely those of the Phasmidt. Again, it has already been shown experimentally that a pin may be passed through the body of a sleeping moth without awakening it. Surely this augment that the insect is not merely reposing, but rather that its fig a outlaptic selum.

#### The Progress of Eugenica

DURING the past twusty-seven mostles more than agency and the past twusty-seven mostles more than agency second there exchanged letters with the Eugenice Second Office of Cold Spring Harbor, N. Y., or matters concerning sonis-spines of sugmined studies. It is a family surfame text cards in the file of the office. These are for use in locating all persons of the same surrance with the same trait—us for example, all the Smiths

riage, all of which letters were received within a space of four months

of four monins of the subject of eugenies has become a popular one for newspaper discussion. Unfortunately the American receiver does not trouble himself to find out the trath concerning the alms and methods of eugenies study. Austing even remotely related to sex highers, infant mortality, forthmarks, budy entitre, sex control, prenalal influences, or to the care, "ene" or treatment of defectives, is given a heading entitled "engenics"—that or that. Some day they will learn that it is only one of the sciences decorded to the promotion of human welfare. Engenies is no more one-ent-und with defertives than with genius. Both are legitimate objects of curent-ent-with greatment of the sciences decorded to the promotion of human of the sciences decorded to the promotion of human one-first that is a task for the chienter that is a task for the chienter—that is not—as one capter recently called it—the latest could implement. If does not propose to undermine the existing social and mortal order, or to undergoine the existing social and mortal order, or to destroy love, but its programment closes and for the intelligent management of defectives.

Fands for the Mawson Expedition are now probably sufficient to complete its work and bring the explorers home, the Commonwealth of Australa having just added 25,000 to its prevous donations. The prese report recently published to the effect that Mawson and his companions had been brought away from Addio Land was erroneous.

#### Motor Roller Skates

ONE of the interesting novelties to be seen at the recent electrical show at the Grand Central Palace, New York, was a pair of motor roller skates, adapted to be driven by electricity obtained from a buttery carried by the wearer of the skutes. The inventor of this machine demonstrated the practicability of the skates by making exhibition runs around the building and also on the sidewalks outside. As shown clearly in the photo-graph, each skate is provided with an extension to the rear, on which is supportextension to the rear, on which is support-ed a small two-pole motor. The armature shaft carries a sprocket pluion, which is connected by chain to a sprocket wheel on the rear roller axle of the skate. The motors may be connected to one or both cells of the battery as desired by means of flexible wiring. Our illustration shows nexible wiring. Our illustration shows the two cells of battery supported by a strap running over the skater's shoulders. However, in the preferred form the bat-tery is strapped to the back of the skater. Current to the motors is controlled by two hutton switches, one for each mot that the skater may conserve his batters by cutting out one or the other skate, de-pending upon which is idle. It will be understood of course that the skater may mercly stand on the skates, setting them be propelled by the motors, or he may skate on them in the ordinary way, using the motors to give him a much greater

#### A Convertible Touring Car Tractor

I N the present sulghtemed age, agricultural rescues are comparatively common and they had early to be still more many the best of the still more than the sulght of the still more distance of the sulght of the su

The car, it may be seen, is an ordinary every day touring car—when the great tractor wheels are left off, of course. The only alteration in it that has been made consists of the addition of a pair of spur gears to the bubs of the driving wheels. see spur gears mesh with much larger gears on the tractor wheels, and with the automobile in "high gear" and a single reduction at the tractor wheels, the speed of the machine is four miles an hour; there is a second speed reduction, for heavier bauling, which gives a maximum speed of only two miles an hour. The whole tractor mechanism is quite separate and distinct from the automobile proper and is merely bolted in place when the er desires to convert his pleasure ve hicle into a working vehicle. the slow rate of progress and the heavy work imposed on the engine, an auxiliary water tank, to insure proper cooling of the cylinders, is carried. A power shaft for stationary work also is provided.

This movel journing our tractor is designed to draw, and actually does draw, three sixteen inch plows in soft or wet ground, and, it has been estimated, replaces from six to nine horses.

#### Protecting Store Windows from the Shock of Blasting

N executing for the new subway runhing mp texination Avenue, New York, a large quantity of rock has had to be binsted. The shock of the dynamite exploitions has worked havoc with plateglass store windows along the line, and the contractors have found it necessary to reinforce the windows. This has been done in a very effective way by the use of wooden supports on each side of the glass, which serve as spreaders for wires that run across the glass to opposite sides of the window frais. The spreaders consist

#### An Aero Yacht

A N enormous flying machine has recent-ly been completed at Dutch Island, A by been completed at Dutch Island, near Savannah, Georgia, by Capt. Mat-thew A. Batson, United States Army, re-tired. The construction of the machine occupied seven months, and it cost \$50, 000. It weighs 5,000 pounds, and the inventor of it claims an additional lifting capacity of two tons. The machine is equipped with twelve large wing planes, one pair having a spread of 391/2 feet, and four pair with a spread of 87% feet, while a sixth pair has a spread of 30 feet. The wings are peculiarly designed with the pur-pose of gulding the air currents inwardtoward the body of the machine and ly toward the body or the machine and there banking them under the base portion of the wings, which are concaved under-neath and carried back along the chassis, so that the currents of air are conducted along the parts nearest the chassis. Any wing or set of four wings or all twelve wing or s may have their angle of incidence changed at the will of the pilot by the turn of a wheel while the machine is in full flight The machine is equipped with three Emersun aeroplane engines, of six-cylinder type installed in the floor of the pliot house. Combined, these engines will supply 350 horse-power, driving the propellers at 1,000 revolutions per minute. Any one of the engines may be thrown out of or into ac-tion by the operation of a clutch. The ability the operation of a cuttor. The cabin of the machine is 27 feet long, and is constructed of cypress paneling % of an inch thick, over which is a covering of canvas. The lifeboat is made of three-ply cypress and sale with inter-layers of curvas. The length of the machine is 74 feet and of the heat? canvas. The length of the machine is for feet and of the boat 33 feet. It is by far the most elaborate hydro-aeroplane ever attempted. The inventor expects to fly across the Atlantic in this machin have yet to learn what it will do in flight.

A Mineral Prospecting Appearatus.—

magazine, and yet they are things upon which the future progress of the world is to be found-It covers fully the discoveries of nce, the schievements of inventors, the feats of engirs and explorers, and the opening of every new field of human endeavor.

Just Bet a Copy and See Fifteen Cents Per Copy A Dollar-Fifty Per Year

A New American Flying Bost (Concluded from page 468.) on the Wright biplanes, instead of being

on the Wright hiplanes, material or being mounted on the extension of the hull as in most other flying boats. A special quadrengular tapered float is mounted beneath the boat about haif way between the latter and the end of the plane, on each side on the usual flying boat cylindrical float are piaced at the ends of the lower plane. The seats for the pilot and passengers ar located in the hull just in front of th nai flying boat cylindrical floats ower plane, and a superstructure is fitted giving the hull much the appearance of cruising motor boat. A starting crank is arranged conveniently behind the pilot's arranged conveniently beamt use photo-seat, and the craft is equipped with an electric motor starter, muffler, anchor whistle, and other fittings used on motor

The power plant of this new boat con sists of a 6-cylinder, 60 horse-power Wright aeronautical motor, which drive the twin propellers by the usual crossed chains. So efficient is the flying boat that speed of quite sixty miles an hour ha ed with two people on board; and it rises from the water after traveling a distance of less than two hundred feet. The speed attained with 80 horse-power shows that the machine is more efficient than the usual type of flying boat in which n motor of from 80 to 100 horse-power is generally used. The machine has shown itself to be very stable in winds and to be readily steered and controlled, for Mr. Wright has frequently piloted it above the Miami and Mad rivers, which are nar-row winding streams in the vicinity of

Another point to be noticed about this new flying boat is the location of the seats strike the pilot or passengers, while the otor is well protected behind the latter On account of the high freeboard and thor ough covering of the hull, the boat should be able to live in a comparatively high sea

#### Baalbek the Mysterious

on a raised platform resting on substruon a raised platform resting on anostruc-tions. The Great Temple ites 44½ feet above the ievel of the plain and is the highest part of the antire inclosure, while the Great Court was only 23 feet lower down. An inclosing wall, the mammoth stones of which have been the marvel of engineers for ages, deserves mention. The lower courses of the waii here are built of stones of moderate dimensions, but they grow rapidly in size, until we come to a grow raphiny in size, until we couse hortest being 63 feet and the longest 65 feet in length, each being about 13 feet high and 10 feet thick. The course of which they form part is some 20 feet above the surface of the ground. They are the largest building blocks ever known to have been used by man, and a still larger one lie in the ancient near-by quarry, never hav-ing been detached from the rock beneath This one is 70 feet long, 14 feet high, and 13 feet wide. Its estimated weight is 1,100 tons, and it is calculated that to raise it would require the strength of 60,000 men. It was probably intended to be placed in the cyclopean wall of the temple inclosure, but some sudden war, pestilence, or revolution must have interrupted the plans of these ancient builders or they would not have expended the labo of years upon this mighty block and then abandoned it still unattached from the

albek's third and last ruin is the pretty little Temple of Venus. It is situated some 200 yards from the other rules. It is an exquisite Corinthian building with gracefully decorated interior. Ow ing to the peculiar arrangement of the interior columns, it has the appearance of an octagon. The entablature supported by these columns does not run continuously from column to column, but recedes in a from column to column, but recedes in a graceful curve aimost to the wall of the cells, giving the whole an appearance of lightness and elegance rarely equaled. In the last century some attempts at renovation were made by the Gives Christians, who converted it into a church dedicated to St. Barbara. It is not now, however, used for worship, and has been rapidly

#### The Manufacture of Hydrogen Gas (Concluded from page \$52.)

ried off through the opened top cover and emerge into the air through the plate iron chinney. The blast is now stopped and the top cover closed down, whereupon the oil spray is set working, and the oil is transformed into oil gas, this below. off spray is set working, and the off in transformed into oil gas, this being obliged to beas through the heated coke of the two generators in succession. In this way all the light as well as heavy hydrocarbons are decomposed and the result is a high grade of hydrogen gas containing from 90 to 96 per cent pure hydrogen. Before the producer is actually working to deliver the pure gas to the rest of the apparatus care is taken to evacuate the gas which was already contained within the pro rs, and the first part of the newly d hydrogen is allowe way of a special valve which is fitted on for this purpose, according to a patented method. During the usual working of method. During the usual working of the producers, the passage of the game through the hot mass of coke causes the temperature of the coke to become eventually lowered, and when it cools down below a certain point there will be no more gas generated. When this is the case, the oil feed is stopped and the hot air blast again turned on so as to fire up. the coke mass as was done in the first Then the oil spray is turned on and the process repeated. Thus the meth od is an intermittent one, and consists in an alternate operation of the oil spray and hot blast. Firing up the coke by the blast usually takes 2 or 8 minutes during the run, that is, when the coke is still hot, then the gas production lasts for about 20

minutes, and so on.

From the second producer the gas goes
by good-steed piping into a device which
is provided with a water seal (shown in
the first engraving) in order to prevent a back flow of gas during the period when er. Care is taken in all cases to keep the hydrogen from becoming mixed with the hydrogen from becoming mixed with air, as is of course quite essential. The gas then passes into the second car by means of coupled piping. On the front end of the car is mounted a well-designed scrubber which is designed with water flow so as to clear the gas of all mechanical impurities such as ash or soot. The scrubber consists of a plate iron case which is filled up with the washing elements of patented makeup, a water flow being introduced at the top, while the gas comes in at the bottom of the scrubber. Means are provided for effectively dividing up the gas flow in small streams so that it comes into as good contact as pos-sible with the water.

Next the gas comes into a cleaner which works on a dry process shown in the illustration, and it is designed to remove any sulphur compounds contained in the gas. Here the cells of the cleaner are filled up with a suitable compound which acts as a filter for the gas. For some uses of the hydrogen, the purifying process can stop at this point, as the garks as sufficiently pure for many industrial uses as may be seen by the following analysis: CO, 0.0 per cant; O, 0.0; CO, 27; CH, 60; H, 96.0; H, 98.0; W 1.8. The secold or rarely of this gas is cent; O. 0.0; CO. 2.7; CH., 6.0; R. 98.0; N. 1.3. The specific gravity of the gas is about 0.10. For such purposes it is not necessary to free the gas from carbon oxide or nitrogen. Next the gas is freed from moisture by sending it through a sul phuric seid dryer pictured in the small pharms and dryer partired at the shart engraving and mounted after the other two devices upon the car platform. Last comes a heating furnace for removing the earlien, oxide, the furnace being heated by carbon, calde, the furuses being beared by call gas. Then the gas goes to a cooler, which is built concluse with the first mentioned sensibles. Analysis is then as fail town: OB, O, OH, -0.07, OD -0.4 per clear; N = 84.4; N = 1.2. Sp. gt. = 0.097 to (9.00).

Figure up, select 1 to 2 hours, and the

ing but two men. The strektp and either sup where too far off, by a special outfit pro-vided with steel gas bottles. To this end a third car can contain a compressor plant these need not be carried to any very great

F you are bound down by routine and the destroying worries and anxieties of a business or profession, you will do well to follow the example of thousands of your fellow men and women who have found mental and physical regeneration in Sanatogen.

They have found Sanatogen to be, not a stimulant, but a true reconstructor of blood, tissue and nerve, a creator of real and fundamental

strength.
Compounded of purest albumen and phosphorus under letters pat-ent, Sanatogen is a natural and healthful food and tonic. It does perfectly and without reaction what so-called tonics do imperfectly and with damaging after effects.

When you take Sanatogen you take what has brought new relish of life to countless men and women, what has won admiring comment from over 18,000 phy-sicians, who have noted its wonderful effects on the nervous and the debiliated.

#### The Fifth Award of the Scientific American Medal

A T the time when the first award of the Schratture A armen. A media was made, various devices were submitted to the committee, and all the seculors seemed to think that the sea directed the most dangers. The successful launching of lifeboots and the discovery of fire seemed to be the most interesting subjects presented. The terrible meanes of condingration won the victory and the saidle was given to a very meritorious fire detecting device. The pursuity of pipes leading to the various holds and bunkers with an electric operated fan to bring up the first weaths of anosite to the bridge has proved its worth and certified to the judgment of the experts, but the lifeboot and its accessories still remained presumably safe. There was no danger, the wireless would bring all the skips in the lanes to attention when the "8-0-8" siznal was fashed and all would be saved. Halls were subdivided and bulkhed doors were closed from the bridge. The sea was robbod of its terrors.

Nawspapers seemed to think that any exploitation of the lifeboat meant some free advertisement of some freak invention. All went well until there occurred ope of the most cruel and unnecessary accidents in the bistory of the world. A proud ship on her maides trip was wounded and sunk in a short time.

Now at this late date we have all reversed ourselves, and the medal so much esteemed on account of the carmed in its award goes to the company that for yearhas been harping on the fact that an adequate number of lifeboats, successfully launched would aure pusselgers and crew until the arrival of succor summoned by withdeam

The American Moseum of Safety as eustodian from year to year of the Nonzwitzio American and other medials given few various anchievements. Sas seen fit through its committee to award it for the fifth time in seven years to the Weiln Marine Equipment Company of Long Island City, N. Y. for "efficient and dependable" devices for award lit for the award contemplates not only a beautiful mechanical schievement in the way of a quadrant davit to which the survivors of the "Titanic" disaster owe their lives in many cases, but also a precidently unshable lifeboat, a non-top-pling block which does not fall after the boat has reached the water and an indestructible rope withetanding the atmospheric conditions for years. It is the Weiln davit and the Jundin decked lifeboat that make up the principal elements of the award. Of course sufficient lifeboats must be provided for all, event fepried mechanism for lowering and casting off and keeping afont have been provided. Herein was the fallacy of

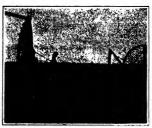

the British Board of Trade rules. The "Titanic" compiled with all the requirements, but look at the result. Now we have lifeboats nested in pairs, athwartships in three or more, stowed on the upper promenade deek

The Scientific American Medal, awarded for the fifth time.

as well as on the boat deck. This is all a step in the right direction.

The Welin davit permits of one or two rows of lifeboats either nested or in tandem being launched from

Swinging out the upper of two nested Lundin boats

either side even with a severe list to port or starboard.
According to this invention the davit turns about a
center moving along guides, and its lower end is in
the form of a toothed quadrant, preferably circular,

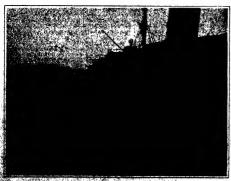

rolling on a rack. The weight of the hoat and its contents tend to make the quadrants roll on the racks, inclining the davits more and more and at the same time moving them outward. The weight of the boat and its live load tend to assist in swinging the boat out over the water. Two sailors can launch a boat containing of prevents the fouling of tackie especially when being raised with no load attached to lower the companion boat.

The Lundin lifeboat was a happy thought which was evolved after the "Italies" disaster. The lifeboat which we liliastrate is as "unstrikable" as a lifeboat cut he made. It is built of steel with cellular bottoms and cannot be smashed, even if a heavy sea crushed it against a huit. The freeboard is bitch, and descenable fonders prevent the staving in of the huit. Folding weather boards a toda out, need to keep out the sea. The boat is divided into eight water-tight compartment by transverse buildheads which earry the deck above the load waterline, thereby unking the boat saif-bailing by means of scappers through the loation of each compartment for imprection and planting. The beats are tested by actually junting sixty men in them and raising them from the ground or over the water. One of the most important exhibits at, the First Internal Expandition of Stefty and Saultation was a pair of Landin lifeboats in operation. There are other accessories such as lowering bolinds, ditting choice, etc., which concern the naval engineer rather than the lay mubile.

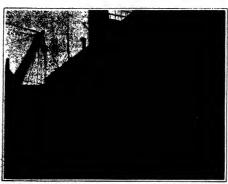

The SCIENTIFIC AMERICAN Medal was awarded on the eresting of becomber 12th, at a banquer given in the great bellroom of the Waldorf-Astoria, New York. Dr. Philey presided. Dr. William H. Tolman, director of the American Museum of Safety, showed interesting sildes of this and other medal-winning devices There were addresses by Dr. Ar. Hadley and Dr. F. R. Hutton, Surgeon-General Stokes and President Arthur Williams.

The other awards were as follows: The Travelers' Insurance Company medals to the "A. E. G." of Rerlin and the New York Telephone Company. The Louis Lidingston Sesman medal to the United States Steel Corporation. The Ratheau medal to the General Electric Company. The Harriman medal was awarded to the Southern Pacific Railway, which was operated for few years without the loss of a single passenger's

Prof. F. R. Hutton made the presentation. The exposition at the Grand Central Palace opened on December 11th with a large attendance, which speaks well for "Safety First." Some of the exhibits will be described and illustrated in a subsequent issue.

The land diff on a markety Disc, thereby the Weltz quadrant davits

Lower deck davits on the "Imperator," an example of good engineering practice.

The Káltor is always stad to receive for examination illustrated articles on subjects of timely interest. If the pietographs are smrit, the articles short, and the facts outlined; the contributions will receive special attention. Accepted articles will be paid for alrequize space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in soitific knowledge and industrial achievement.

#### The Decline of the United States Navy

HE United States Navy is declining Under the policy of the present administration it is declining at a rate, which, if maintained for the next ing at a care, which, it maintained for the flext four years, will place it in the fifth posttion, below France and Jupan, and will reduce the United States from a first-clines to a second-class naval power. We have on our dock a public document, showing the relative position in sea strength of the United States Nava.

Navy, which is published by the Government at the Navy, which is published by the Government at the close of each year, and is sent out for the information of the taxpayers of this country. The document is headed, "Office of Naval Intelligence, Navy Department," and it is prefaced by the following suntenent: "In order to answer the frequent inquiries of societies and persons throughout the country interested in the maintenance of the navy and its relative strength and importance in comparison with foreign mavies, the following information has been compiled." From its tables we learn that Great British has built and is now build-ing warships of a total tomage of 2,501,201 tons; that Germany is represented by 1,228,208 tons; the United States by 921,844 tons; France by 876,155 tons; and Japan by 702,000 tons

We say that the United States Navy is declining be cause a comparison of this document with those issued from the same office in previous years shows that, whereas two or three years ago the United States Navy stood second in strength, with a decided lend over Germany, and France and Japan were so far behind this country as to be entirely outclassed, conditions are so far changed that to-day the German may is one third more powerful than ours in total tonnage, France is crowding us closely for third position, and in three or four years' time, at the present respective rates of construction, Japan will have a navy equal if not superior to our own.

We make these statements unreservedly; for they are based on cold governmental statistics. Anyone who reads these lines is at liberty to write to the Navy Department and secure copies of this document, and probably of those of the few years preceding.

probably of those of the new years preceding.
The decline of our Navy, however, is more serious—far more serious—than is shown by these mere figures of total tomage. The building by Great Britain of the first dreadhought is few years ago established an entirely new rating of mayal strength. The all-big-gun dreadhought of the future will be the deciding factor in a mixel campaign. More than ever before, the ship and the gun will decide the fight. Our gunners are doing good work in target practice; but the write doing good work in arger practice; out the writer has direct evidence that it is no better than that it some other navies, and not nearly so good as is being done to-day in one particular navy. Therefore, in a future senight the nation that can string out the longest line of dreadmoughts, carrying the greatest number of long-range armor-piercing guns, will win the fight.

liaving this in mind, let us see how we stand. Great Britain to-day has built and is building 42 dread-noughts; Germany, 26; the United States, 12; France, 11; and Japan, 10 drendnoughts.
We commend to the attention of those me

Congress who waste the time of the nation in feelish talk about the sin of building big gues and ships to cars; then, the following indisputable fact, namely, that if, in a comple of years' thus when all these slips are completed, the Justed States Navy should be sent out by this same Congress to meet the dreadnought fact. of Germany in a stand-up fight, it would be doomed, not merely to defeat, but to absolute annihilation! To the small-navy men in Congress, we commend also the consideration tint, if they dispatched our fisct to fight either that of France or Japan, we should prob-ably win, but at a cost of loss in ships and damage to those which remained affect, that would relegate us to the third-rate position occupied by the Russian Navy at the close of the Russo-Japanese war.

at the close of the Russe-Japanese war.

The silly talk about "navab holidays," the "criminal expenditure for battleships," the "combination of warship building frams to promote war scares," to say nothing of the unctuous moralizing of the editorial writer who cemes late to his deck and is hard up for a subject—all of this and much more is due to a total misunder—all of this and much more is due to a total misunder standing of the purposes of a national war fleet. The money put into a country's navy is spent for national insurance. To preserve the peace, prosperity and honor of the United States, we are at present investing about e and a quarter per cent only of the national wealth of this country in our Navy. Is that a wicked extravagance?

The present deplorable decadence dates from the time, two or three years ago, when Congress refused to continue the policy of building two istitieships a year—an addition which our Naval Board had decided was large enough to maintain the navy at a strength sufficient to meet its responsibilities. sumetent to need its responsibilities. In two succes-sive years, Congress so far lost sight of its proper func-tion as to play fast-and-loose with this recommenda-tion of its naval experts and cut the appropriation from two battleships to one, although making no corresponding reduction in appropriations for auxiliary ships

We had hoved that the new Secretary of the Navy. whose work as the Editor of a paper should, at least, have developed in him the halilt of taking a broad point of view ou all subjects, and especially on those of a national character, would have loyally followed the policy and adopted the attitude of his able predece and bent his whole energy to restoring the material strength of our navy to that standard which the Naval Board had so wisely advised. This he has failed to do; and in his recent recommendations to Congress, indo; and in an recent recommendations to Cangress, in-stead of asking for the four battleships decided upon as necessary by the Navai Board to repair the deficien-cies of the two previous years, he is asking for two only. Mr. Daniels lacks a true perspective and a proper sen of proportion. We wish that his elequence on hebalf of his pet idea, good as it is, of making our warships more than ever schools of training for young men, had been directed to hammering into the heads of Congressien the really hig facts of the naval situation as we have outlined them above

It has been the privilege of the writ r to live aboard ship for extended periods and get into quite intimate touch with the soumen and marines. He found them to be a remarkably intelligent and well educated class of young men, who, while they fully appreciated the opportunities for instruction (now afforded and prosed to be extended) offered by enlistment, were far more interested in the question of the hitting power of their particular ship and the ability of the fleet as a whole to "whip" any equal fleet to which it might be opposed.

The Scientific American is heartily in favor of everything the Secretary can do within reason to render the life of the entisted man attractive and uplifting, the life of the emission and attractive and updating, but we cannot but feel that in the promotion of this particular object, Mr Daniels is losing sight of the larger things, and failing in that broad information and statesmanlike point of view, which should be the indispensable characteristics of the head of this great iustitution

#### The Scientific American in Our Schools

ROM its very first number, published nearly seventy years ago, down to the very last, the Supervising years ago, down to the very man, one Supervision and, we hope, a distinct educa-tional force in this country. As a scientific newspaper it has endeavored to set forth simply and accurately the achievements of technically informed men, the world over. So rapid is the march of science, engineering, and industry that the textbook of to-day is all but and industry max the textbook of fo-day is all pur obsolete to-morrow, and so enormous is the amount of unterial presented to learned societies for considera-tion, that even university lecturers find it difficult to keep abreast of the advances made in their own special field. Only a popularly worded periodical, which can held. Only a popularly worden periodical, which exists for the sole purpose of digesting the results of scientific investigation and of presenting them in such form that the layman may read them understandingly can really supplement the class textbook. In the course of time the Scientific American has become, as a result, something more than a journal to be read during of time the "CCRETIFIC AMERICAN has necessarily assult, something more than a journal to be read during an idle hour. It has become in truth a kind of popular illustrated weekly, encyclopedia of zechnology, and as such it is treasured in perannect bound form not only in the fibraries of the more important schools and universities in America and E a general interest in scien

a general interest in science. We are impelled to make these observations and of the extensive aditoral concentrations. While not contest "What say the Ten Greatest between those of our Tuner" was in progress. To be make knew that many a young sane, has received the accurate impression of the wax world of thoughty the pages of the Schmatterio American, and that is a boy with a natural bent toward science or sugit a boy with a natural bent toward setons of suggested ing was encouraged by its pages in ellipsing to dis-belled that among the ranks of professional engineers, physicists or chemists, he could accomplish its life most successfully. But we did not know, as the estri-spondence revealed, how very extensively the Scrustrysia August 18 amplious the trackers to this state account AMERICAN is employed by teachers in their class rooms.
One instructor made the articles in the journal the subject of weekly essays to be written by his pupils; another used it to illustrate lectures; a third '(and it seems that there are many like him) selected the more important articles as they appeared from week to week for class room discussion. The subject of the contest what are the Ten Greatest Inventions of Our Time?"
ient itself peculiarly well to class room work. No two
thinking human beings are quite in accord on the enpracetest inventions of our time. Veritable debutes apparently ensued in many schools throughout the country, if we may judge by the votes of pupils on the subjetaken by school teachers.

The gratifying interest, which was shown in the con-test leads us to ask school teachers if the SCHENTIFIC AMERICAN cannot be made even more effective for school use than it is at present. While the point of view of an editor—particularly the editor of a popular scien-tific journal—is not unlike that of a teacher in many respects, nevertheless the suggestions of teachers abould prove highly illuminating. The Editor of the Schri-TIFIC AMERICAN would therefore appreciate it if those American more or less regularly in their work would et down their thoughts on the subject and send th

E think of Napoleon as the great Lord of War, the butcher of human live War, the butcher of human lives, the build-er of a great empire, built only to fail even, before the death of its founder.

before the death of the foundation. It is well to remember that his genius was great in also other, more hatingly fruitful fields. He was not only a great warrior, but also a great statesmen—and as such he did not full to resilise the importance to the community of arts and sciences

Writing to the astronomer, Oriani, from Milan, which

he had entered in triumph, Napoleon said:
"The sciences which do honor to the human mind and the arts which embellish life and perpetuate great achievements for posterity, should be especially honored

under free governments. . . . I invite the scholars to meet and to give me their opinious as to the means that should be taken, and the needs to be fulfilled, in order to bring new life and activity into the sciences and the fine arts.

are ann activity into the sciences and the nine arts. Those who wish to go to France will be received with distinction by the government. The French people set a higher value on the acquisition of a skilled mathe-matician, a celebrated painter or a distinguished man of any profession, than upon the possession of the largest and richest city."

A Remarkable Aerial Cableway, about 75 miles long, is soon to be built across the mountain barriers separating the famous Vale of Kashmir, in the Indian native State of Kashmir, from the plains of the Punjab. It will be by far the longest cableway in the world, says a consular report on this subject the longest at present being one of twenty-two miles in Argentina. The plan of constructions of the plan of contractions and the same of the plan of to the off control of the control of the control of construction an ordinely' railway late Kashudr has been pronounced impracticable on account of the lease congionerate nature of the soll in this part of the Hensilaysa, which causes insumerable slipe and the fights of huge boulders with every heavy rain. The previous carriage road into Kashudr, extending short 300, sales between Ravalphald and Stangar, was east be suit, with the greatest difficulty, and with match least of the description of the country of the control of the country of the of constructing an ordinary railway into Kashmir

A Section of the second of

#### Bugineering

Especimental Fragores Trislan—The Great Western Balless Company has put in service two experimental, rhospecto trains, each consisting of four care. The care are built suitedly of setod, and they are lighted throughout electrically. Wood has been practically eliminated from these basins. The only wooden construction is the foot-board on the outside,

Railway Accelerate in Assertica.—During the first quarter of 1913, 195 persons were killed and 2,025 were injured in train accelerate. In other than train accelerate, including accidents to employees and to peasangers and treepassors, 2,098 were killed, and 17,194 were injured. Industrial accidents on railroads, not involved in train operations, accounted for 57 killed and 36,812 injured.

and 28,812 injured.

Marinase as Englasmen and Trainmen.—Under instructions from the War Department, marines from
the marine barracies, Camp Elilott, I. C. Z., Panama,
are plying to and fro on the regular passenger train
engines of the Panama Railroad, armed with letter
requesting engineers to give them all possible instructions relative to engine running, etc. This movement
is being inaugurated for the purpose of having men
in the marine service who can be promptly put in on
railways in an enemy's territory to handle motive
power and trains for the transportation of troops and
provisions.

The Great Ealway Tunnels of the World—The world's greatest tunnels are to be found in Europe and a brief summary of these in the Engineer shows that the greatest is the Simplon which is 12½ miles in length. The, the St. Gothard and Lotscheng, are over 9½ miles in length. The Mont Cenis is a little over 7 miles in length. The Aribers, in Austria, is 5½ miles long. There are four tunnels between five and five miles and six miles in length, five one where four and five miles in length, seven between the and four miles, and six miles in the second tree and four miles, and sixteen tunnels that are over two miles long. The longest tunnel in this country, the Hoosac, is four and one third miles long.

Land-seasuse Rairead Cara.—Few improvements of late years affecting the on vendence of the railway passenger are more important than the innovation now being made by the Pennsylvania Railroad in runing between New York and Philadelphia a steel lunch-counter car. All travelers between big cities on important fast train can bear testimony to the innovaecience of waiting for a seat in the dining car. The lunch-counter car will be a greet saver of time, and well obviate much inconvenience and irritation. It is 30 feet long and has a mahogany counter running half its length. Twenty-one persons can be seated, and the counter has every convenience, even to a cigar hundder.

has every convenience, even to a cigar humidor. Sebway Line for Mina.—The principal cities of Italy are considering the matter of installing subway lines in order to handle the ever-increasing traffic. We have mentioned the recent project for a subway of some length at Naplas, and it is now stated that he city of Mina is considering the feasibility of running a subway line. The municipality appears to be in favor of the new scheme, especially because in the inner part of town there are many narrow streets which hinder the proper extension of surface traction lines. One drawback toward carrying out the engineering work on the tunnel is that the subsoil is not of a very good character for this kind of an enterprise, so that some special measures will probably need to be taken.

Giant Coffer-dam for the Equitable Building.—A vast reinforced concrete monolithic foundation is being built entirely account the area upon which will be erected the new Equitable Building in this city, a structural which will contain one million equare frest of restable floor space, and will tower slott to a height of thirtysix stories. The coffer-dam will be a solid concrete wall, six feet broad and nighty feet deep, extending cighty feet to sold rock. This will be the largest office building yet constructed. It will weigh over 200,000 tons as against the weight of 100,000 tons of the Woolworth Building, 185,500 tons of the Municipal Building, and 52,550 tons of the Singer Building. The steel framework alone will weigh 50,000 tons, as against 25, 000 tons required for the Woolworth Building.

000 tons required for the Woolworth Building.

The Meet Powerful Electric LocessedVess.—The New York Centest Railroad is having built for its terminal electric service six electric locomotives which will be espable of developing 2,000 horse-power continuously or 2,000 horse-power or one hour. They will be espable of developing 2,000 horse-power outsinously or 2,000 horse-power or one hour. They quit less transitionally or 2,000 horse-power on this per hour as the one-hour rating. Each locomotive can haul, if necessary, a 1,000-ton train on level teach, continuously, at 90 miles per hour. They are insulated for 1,200 wells to espain the future, should it be desired, to openie out this votage. They are being built by the Quessel Electric Company at Schenectady. They have a higher efficiency than any other high-speed electric locometers yet constructed.

The Next International Geological Congress will meet in Brussels in 1917.

The 1914 Meeting of the American Association for the Advancement of Selecton—The American Association for the Advancement of Seionce will hold its next convocation week meeting in Atlanta, (a., from December 20th, 1913, to January 3rd, 1914, under the presidency of Dr. Edmund Beccher Wilson, of Columbia University.

C. Francis Jenkins a wasted the John Scott Medal.— The Franklin Institute of Philiadelphis has just amnounced the ward of the John Scott model to C. Francis to C. Francis and the John Scott model to C. Francis in model of the John Scott model to C. Francis Institute to M. Fodicis for original research in this set, the first being an award of the Bliott Cresson gold model 1885) for the discovery of a uncoestril method for projecting motion plotares on a large canwa; which subsequently made possible the thousands of thesiers in which photo plays are produced. Much of his old experimental apparatus was acquired by the National Museum some years ago, and is now on exhibition in the Grafte Arts Section.

Standard Adopted for Weighing Precious Stones—Incident and includer recently issued by the Bureau of Standard, Department of Commerce, announcement is made of the recognition by the Bureau after July 1st, 1913, of the metric caract of 200 milligrammes as the standard of the precious stones, and the standard of weight for diamonds, the staide above all upon which there should be the best agreement as to the unit of weight for diamonds, the staide above all upon which there should be the best agreement as to the unit of weight for diamonds, the staide above all upon which there should be the best agreement as to the unit of weight for diamonds, the staide above all upon which there should be the best agreement as to the unit of weight because of the great value of the commodity. Recently the movement for uniformity in the standard rapidly gained ground, and Spain, Italy, Bulgaris, Deumark, Norway, Japan, Portugal, Roumanis, Switzerland, Sweden, France, Germany, Holland, and Bolgium, with the United States, are in the list of those countries which now use the new international standard. England is the only country of importance in which the change has not as yet been made, but quanderable progress toward that end has been made even in that country.

The American Women's Table.—The Naples Table Association for Promoting Laboratory Research by Women was founded in 1818. It maintains a research table at the Zoological Station at Naples for qualified women students and since 1853 has offered every two years a research prize of \$1,000. The Zoological Station at Naples was opened by Prof. Anton Dohra in 1872 for the collection and study of biological material. It has developed into an international institution offering opportunities for independent research in general biology and physiology. Dr. Reinhard Dohra is the present director. The station provides all material free of cost and the American Women's Table is sometimes used by four or five research students in the course of a year. The Ellen Richards Research Prize of \$1,000 is offered periodically for the best scientific thesis, written by a woman, embodying new observations and new conclusions based on independent laboratory research in biological (including psychological), chemical, or physical science. The seventh Ellen Richards Prize of \$1,000 for the best thesis written by a woman, on a scientific subscience. The seventh comman, on a scientific subscience in independent processing and new conclusions based on independent prize of \$1,000 for the best thesis written by a woman, on a scientific subscience. The seventh Ellen Richards Prize of \$1,000 for the best thesis written by a woman, on a scientific subscience. The seventh Ellen Richards Prize of \$1,000 for the best thesis written by a woman, on a scientific subscience. The three of offered in competition are to be presented to the executive committee of the association and must be in the hands of the committee of the sacrostation and must be in the hands of the chairms of the committee on the prize, Dr. Lillias Weish, Goucher College, Ballimore, Md. before February 26th, 1915. The title page of each manuscript must bear an assumed name; and the writer must send with her amanuscript as selled envelope containing, her application blank and superevente

#### Automobile

A Novel License Tag.—An automobile tag, the body of which has a particular color indicating units of one thousand or more and upon which a number is produced indicating units of nine hundred and ninetynice or less, has been patented by Abram Wakeman of New York city, patent No. 1,073,004.

An Automobile Funeral Car.—In a patent, No. 1,772,844, Ida Schmidt Marvin of Detroit, Mich., presents a fineral car in which a compartment to receive a easket is located in rear of the space for the chafficur and a large compartment is provided in the rear of the casket space for passengers.

A Convertible Automobile Body.—Patent No. 1,072,—394 has been issued to Frank E Plummer of Washington, D. C., assigner of George C, Plummer of the same place, for an automobile body and presents in consection with a fixed front sead, a rear section having a removable seat and conventional sides and done and sildable on the chaosis to telescope the front seat, so that the body may be converted from a road-ster into a delivery or tourning can.

A Simple The Tube Tester.—The patient No. 1.071,—128, to Dover Stamping and Manufacturing Company of Portland, Manne, assignor of Horace E. Wilatuey of Cambridge, Mass, shows a tube tester whose tank has its bottom curved in vertical plane and a rod adjustably someted to the tank extends upwardly and has its upper end bent to form a hook on which the tuber may be suspensed and along which it may be moved in moving the lower part of the tube through the water in the testing tank.

Good Roads, Electric Lighting and the Contral and properly equipped they should be provided with and properly equipped they should be provided with detertive lighting, to enable them to be safely traversed by light as well as by day, and when the electric wring for legiting purposes is installed, it will bring with it to the property of the contract of the property of the property of the contract of the property of the contract that provided during the non-post period of the day would simplify very maternally the financial element in the equipment of the road with electricity, and, when combined with the ultimate business of supplying residents along the route with light and power, should load to a most extended development of the electrical industry. It must be renembered that although the kinematograph was well known for many years, the immensusions of the property of the provision and distribution of suitable films was provided. In like manner the real development of any systematic roadside equipment of the approximation and continuous of a systematic roadside equipment of charged and standardized exchangeable batteries, so that an immediate supply of current can be obtained as readily and as cheapyly as a few gallines of gasoline. When such a field for business appears before the electrical development muduatries, it would seem as fit its exploitation would depend only upon the time required for the construction and installation of the equipment.

Why Not Interchangeable Storage Batteries for Automobiles? - The relations between the unprevenent of highways and the extended mee of unchanically-propelled velories are very generally understood, but it is possible that the influence of the good-roads invesement upon the development of the electric automobile is not so definitely perceived. Already the increasing cost of gasoline is narrowing the gap between the operative cost of the two kinds of motive power, and it is possible that improvements in the efficiency and consense of the two kinds of motive power, and it is possible that improvements in the efficiency and consense of the two kinds of motive power, and it is possible that improvements in the efficiency and consense of the two types of unchange to be fully realized. The owner of a supply of electric current for vehicles which needs automobile are to be fully realized. The owner of a submobile are to be fully realized. The owner of a submobile are to be fully realized. The owner of a submobile are to be fully realized. The owner of a submobile are to be fully realized. The owner of an automobile are two two fully realized in the production of the control of the

## Inspecting Track Scales for the United States Government

#### New Test Car and Equipment of the National Bureau of Standards

By Herbert T. Wade

THE United States Government, through its Bureau of Standards of the Department of Commerce, recently has put into service a special standard testweight car designed especially for testing the track scales on railways and the weighing equipment of grain elevators and other establishments where com-modities are weighed in bulk for the benefit of the general public, which unlike the great corporation is rarely eral punic, which unine the great corporation is rarely able to protect itself by official tests of the scales or weighing mechanism on whose indicated weight they pay freight or purchase commodities in bulk. This test car differs from those customarily employed on American rallways in that the test weights are more carefully standardized and are used with a test tru only when the scales are under examination, instead of truck, car and weights together forming the test weight. This has involved a special form of construcweight. This has involved a special form of construc-tion and equipment which was especially designed for the Government after general plans by L. A. Fischer, chief of the Division of Weights and Measures, and C. A. Briggs, assistant physicist in charge of the car, by A. H. Emery of Glenbrook, Conn., well known as the designer and builder of the famous Emery testing machine of the Bureau of Standards.

The test car, which was built by the American Car and Foundry Company at Wilmington, Del., and then

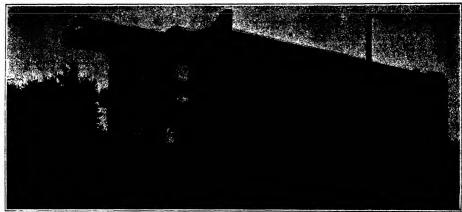

The principal feature of the equipment are the test weights, which are special castings of selected iron whose weight has been ascertained with high precision. These include eight 10,000-pound weights and four 2,500pound weights, large blocks or slabs of iron which when the car is in motion are held rigid, boited firmly to a framework. There are also cases carrying an aggregate of 10,000 pounds in 50-pound weights to be use on, stock yard, grain elevator or other scales, the car carrying a comp ing, examining and sealing all of the various types of scales and their weights of large capacity.

The standard weights and also the cases of separate weights are fitted with a special recess or socket which a coupling connected with the cable of the o head holst can be inserted and the weights raised by the tackle with safety and expedition. These weights were standardized by first securing a series of 50-nound were used to derive a series of correct 50-pound weights. were then calibrated, and these in turn were che against each other and were used to standardize the 10,000-pound weights, so that when finally adjusted, correct on an average to one tenth of a pound in 10,000, they showed that the 90,000 pounds of large weights

geer from motor to axie the track can be moved the track and take any position desired along the scale or the adjoining rail.

This truck, which has a wheelb 5,000 pounds and can be used as a test weight it on the scales over the various sections to be read then the standard weights are added and the and its load is placed again on the scale and the of the truck subtracted rous has resonant, or, sur It is not even necessary to me the truck, for their and weights could be deposited directly on the scales, but the truck is most convenient as truck, are usually tested by placing the standard weights each of the various sections or bearing goings a sively and noting the variation in reading

The functions of the test weight car are considerably more extended than the ordinary test weight cars of the conditions under which it is operat car furnishes properly authenticated weights of large denominations, hitherto lacking, which serve as stand-ards to standardize other large weights by direct com-It affords opportunity to test th of large capacity scales and weighing machinery us in commerce and industry, by direct application of

Inspecting track scales for the United States Government

equipped by Mr Emery is unique in many respects In appearance it resembles an ordinary automobile car, on which, in fact, it was patterned, being of first-class non-collapsible construction, with United States stand-ard equipment. It cost the Government \$14,000 complete, the testing equipment representing a much greater expense than the car itself, and with its various appliances it is really a most thoroughly worked out mechanical laboratory for the purpose intended. equipment the car weighed complete on the scales 172. at Bridgeport

It is rated at a capacity of 100,000 pounds according to railway standards and has an inside length of 40 feet 5 inches, an inside width of 8 feet 10 inches, an inside height of 9 feet 1 lnch, a height at caves of 12 feet 10 inches, and a width at eaves of 9 feet 2 inch a coupler shank 5 by 7, yoke attachment, K2 triple-brake valve, No. 2 metal beam, and Westinghouse draft

The interior of the car is divided into two ments. One where the standard weights and truck for their carrying as well as the crane for handling them are located and a smaller compartment in which are installed a gasoline driven electric generator of 10 kilo watts capacity supplying power for an overhead host, for the truck carrying the standard weights on the scales, and current for the lighting circuit of the car. being also a small storage battery for this last see when the generator is not running. It further amodations for the inspector and his two

re correct within an error of one nound or one mert ance for the highest class of standard weights tested

The hoist by which these weights are handled is the leading mechanical feature of the car. girders from which the crane operates is carried just under the roof of the car by special arches in its fram-Normally this is stowed entirely within the car, but when a test is to be made the large doors at th they overhang the end of the car sufficiently to enable the track to be lifted out from its position within the car and the various weights as desired to be placed upon it according to the test amount desired

e hoist, of course, travels along the overhead rails, picks up truck or weight and transports it out above the track, where the load may be set in position, the power being supplied from the generator and the When it is realized that weights of 10,000 pounds mus be handled safely and speedily the care with which the overhead crane was designed is apparent, for the entire series is loaded or unloaded on the truck well within

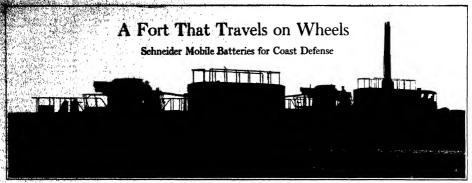

The truck, which also is carried within the car, bolt ed rigid to a wooden framework when not in use, is a six-wheel carriage designed to carry the test weights. It has a 5 horse-power electric motor, which can be supplied with current from the generator through a portable, flexible conductor and by means of a worm and

ndard weights. It also enables the mi d in establishing the weights of the test cars of the various railroads to be accurately standardised, and an examination to be made of track and other large scales as they are maintained by tests either simul

With the new car the Government officials hope to determine the equipment and tests required properly to test, adjust and maintain large scales, as well as study chanical action of the scales in relation the mechanical action of the scales in relation to their proper design and chargeter, and especially as regards their rating, for it is believed that the numerical rating of many scales is far in excess of their actual capacity. It is further the intention of the Bureau of Standards to study the question of scale specifications for the proper design and purchase of scales by the Go and private individuals and to study weig and conditions in general with a view to the and continuous in general with a view to the e tion of those factors which are condactly to me and bad weighing practices. Finally to determine variations are to be expected with the different modifies and to secure statistics and other into for the determination of proper telerances in

and weighing. With these ends in view the Buyeses of Simular car has just made its initial trip though New Jones and proliminary, results have made the highest had sequisition by the Government. There has many general overshalling of trends weights the this travels the importance of the medical that there have been provided in the contract of the medical that the provided that the contract of the medical that the provided that the contract of the medical that the provided that the contract of the medical that the provided that the contract of the medical that the contract of the medical that the contract of the con

200

#### THE COMPLETE SCHNEIDER COAST DEFENSE TRAIN AS BATTERY

M OBILES batteries running on rails are well quali-dent if posethle to do away with batteries which it would be otherwise necessary to provide for the efficace of areas included between the principal defensive forti-cations. By reason of their great mobility, these bet-

cations. By reason of their great mobility, these batteries can be rapidly moved to points where it is necessary to reinforce the defense, to enter immediately into action, or to withdraw, either because they may be required deswhere or to escape a well-directed free. The temporary consolidation of a certain number of gues will constitute a kind of movable fort, powerful and very economical. The mobility of the betteries will be a protecting element far more effections than the remparts of permanent forts, upon which, because of the advanced testition of the outworks that five of me the reimpers of permanent inits, upon which, because of the advanced position of the outworks, the fire of an enemy can be concentrated. In addition to these various advantages, mobile bat-teries juivenit other merits, the principal ones of which

fixed coast batteries of the same offensive power, but of much more coatly construcpower, but of much more courty construc-tion, there is great occusiony in the prep-aration of the defense. It is necessary merely to provide a rativary. (a) Complete servey of the plan of defense, since the plantag of a battery in

position is not betrayed by prelim

(c) A better utilisation and economy of material, since the guns will not be use-lessly stationed in fixed positions in per-manent work.

(s) The material can be more easily kapt in condition; for in time of peace the batteries can be stored under cover and

red from intemperate weather. (e) It will be unnecessary to establish strategic roads for conveying stege or field artillery material on wheels.

(f) The railway can be employed for (7) The rainway can be employed nor other purposes than those of the artillery. Thus in time of war it can be used for the rapid transportation of infantry and the conveying of the necessary ammunition to the defending batteries; and in time of peace for the economical development of the coast by the transportation of merchandise and passengers. The system herewith illustrated has been de veloped by Schneider

& Co., the well known makers of armor and guns.

The Battery.— The mobile buttery consists of two massive steel cars, each carry rapid-fire gun, an and an observa constituting a ing an 8-inch ammunition car, tion car, the whoice train of four cars drawn by a loco nary railway. The motive on an ordigun car is provided with two bogie steel platform, low trucks and a sheeter in the middle than at the ends in which lower part the 8-inch piece is carried on mount. The gun are similar to coast-defense a central awiveland its carriage by Schneider. The the frame, and the of the car,

Observation car with fire-control officer at the top of tele telephone connection.

brakes are all similar to the corresponding parts on the ammunition car.

The observatory consists of two morable tubes, tric-

scoring one within the other and of a short fixed sec-

tion of tube carried on the car itself, and extending down to the frame. The fixed tube section serves to guide the movable sections. The movable tubes are telescoped into the fixed tubes when the train is traveling to its destination. The smaller movable tube has an observation piatform at its upper end. The tower is operated by means of a hand-operated hoisting apparalus within the car.

The gru has a caliber of 8 inches. Weight of projectile is 220 pounds; initial velocity, 1,400 foot-seconds; total length of the gun barrel, 11 feet, maximum elevation, 60 degrees; maximum depression minus tive degrees, are of fire, 360 degrees; weight of the gun without breech blocks, 3,560 kilogrammes; weight of the breech block is 140 kilogrammes; weight of the entire gun mounting and car, 1,145 kilogrammes. hydrantic recoil brake is so constructed that the recoil can be readily taken up by the truck and the rails of the track. The mechanism for returning the gun to battery is sufficiently powerful to bring the piece into position, even when the gun is trained at the maximum

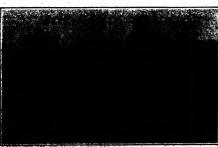

angle of fire. The side members of the platform carry two articulated swinging supports, the outer ends of which carry screw-adjusted base plates, which are employed when the gun is swung around with its longitudinal axis at right angles to the iength of the car Ammanition is served to the gan by means of a small carriage, which runs on a circular rall surrounding

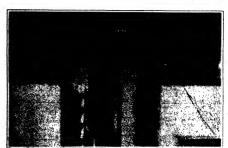

The Ammunition Car.—The ammunition cur is placed between the two gun cars in the train, so as to supply both pleces with projectiles The projectiles are slored in racks arranged within the car in a horizontal position The car is armored with plates one luch in thickness.

The Observation Car.-The observation car is usually coupled directly to the loco-motive. From this position the commanding officer can place his guns in the most favorable positions, or to select a more advantageous

point of observation

The observatory at full extension provides an excellent platform for spotting the fall of the shots.

Interior of ammunition car: crane picking up shell from the shell rack.

A THE PROPERTY OF THE PARTY OF

ONE of the most puzzling problems in physics for the layman is the climbing ability of an seroplane. Nor do daily papers—or aeronautical magazines, at that —ever explain just why it was so difficult for Mr. X to fly the hundred feet higher than Mr. Y, for which they praise him so freely.

they irraise him so treety.

Throwing some light on this question means, incidentally, elucidating some of the dark corners of the whole vexed problem of flight, which, after ten years oplaning, does not yet seem to be understood as well as it should be.

Credit is due to the aviator who breaks an altitude record on two grounds: First, that he has the skill instinctively to fly his machine under the most favorcal conditions and to "get out all there is in shle physical conditions and to "get out all there is in it"—In other words, always to choose at angle of his planes that wastes least power. Not many people realize how much superfluous power and fuel may be uselessly expended in flying; for it would take com-plicated calculations theoretically to define the most economical angle of the planes under varying condi-tions of air and wind, and for a given type and condi-tion of machine and motor. It is an important element of the maket and moore. At some important extraction of the maket angle is best at a given moment, and, incidentally, how he must move his rudders and controls dentally, how he must move his rudders and controls that they, too, uttack the air at the most economical angle. In the birdlike nerophase of the future, with "feathering" propeller blades, it will be still more important to schap the angle of the propeller blades to

changing conditions.

The second schievement for which credit is due to the pilot is purely humau-to have retained full comthe phot is purely numau—to mave retained run com-mand over high faculties under the intense discomforts of very high fights. With many phots those include something closely akin to dizzluess; but all suffer from the Arctic cold and the rar-fled air, though this could

be eliminated by heating and oxygen.

But why is it so difficult for the instrument, the
machine, to fly high? Simply because it is so difficult macune, to ny night Simply because it is so difficult to fly at all, because the air is so thin and light. If it were as thick and heavy as water, we would need no wings and motors, we could swim in it with our mare legs and urms. But because it is thin, we need large wings—to get hold of much at a time—and we need strong motors, because such wings are so difficult to make light and strong, and must be supported by wires and struts, that it takes great power to move all these encumbrances speedily through the air.
And speedily driven they must be, because otherwise
the wings would have to be of a size wholly impracticable

Now if the air becomes twice as thin and light at a certain allitude, all these difficulties of flying become exactly doubled. To fly with the same power at au altitude where the weight of the air is only half as great would render it necessary that the area of the pro-peller bindes of the supporting planes, and last, though not least, of the rudders and controls, be exactly doubled without either increasing their weight or the thick ness and number of the wires and struts necessary to support them Obviously, we cannot do this; and it follows, therefore, that any ordinary seroplane becomes a "racing machine" with "abnormally reduced" wing area, as soon as we mentally place it in such thin air. In short, it behaves as though we had halved the area of its wings, its propeller blades and its con trols, without increasing its motive power, and now wanted to fly it near the ground. If the machine has been designed, let us say, with so much surplus lift near the ground for extra passengers and great stores of fuel, that it can still fly with one man and little fuel after having all its surfaces reduced one baif, it is certaln that it can climb in its normal condition, and with one man, to an aititude where the density of the air is half that at the ground | Incidentally, it there becomes a racing machine—its speed is just as much increased as it would be at the ground, if the wings were reduced to half their size. But not fully, because racing machines for good reasons are not in the habit of reducing the area of their propeller blades as well. the large blade area and relatively small wing area which made the "Baby Wrights" at Belmont Park in 1910 look more like "helicopters stood on edge" than

Thus far we have not considered the "aititude troubles" of the motors, because these are more of an "aerostatic than an aerodynamic nature". To preserve the same power in the motor with the sir's density re duced one half, would also require doubling the cylli volume, other conditions, such as the quantity of fuel for each stroke, being equal. In the same size of cylinder, only half as much fuel can be consumed per stroke at such great altitudes as at the level of the ground. But carbureters in which the amount of fuel per stroke depends on the energy (and, consequently, density) of an air jet, regulate this proportion more or less automatically.

## SCIENTIFIC AMERICAN

There is still another way to look at the physics of high flying, though not quite as efficient in guarding against contained and copilaties: the litt of an accepiane is always a fixed ratio to the pull of the propeller, or the drift. If the sir's density is one ball, the propeller must run much faster to get the same pull; for, in the propeller the pull is likewise a fixed ratio of the "drift." of the blades, or the turning effort of hemotor. This shows at once how a propeller must recessarily race at great altitudes, and why Garross broke a connecting rod while making a new height record. But why would a larger propeller nust cause of the sophlems to which, for instance, some critics of Frod. A. G. Reli have failer witch, when he suggested racing from America to Europe at the height of several milesquite an absurd proposition. It does help, antely; a large propeller is always good, as the Wrights have demonstrated for all time. The writer expects larger propellers with bindes feathering at will during flight (and reversed in safe leadings). Enlarger rodders, There is still another way to look at the physics of properties with bindes returning as will during high (and reversed in safe landings). Enlarged rudders, whose usefulness has been so well demonstrated by Prgoud, and the angle of the planes adjustable against the fuselage or body (or rather the line of the pro-peller's pull), as tried by Gallaudet for a short start en increases of lift, may become standard feat nd sud and sudden increases of int, may become standard rear-ures of the "birdlike" aeroplane of the future, but it does not help enough. It only prevents the slip from increasing in the thinner air. If weight did not prevent carrying more than two large propellers side by side, carrying more than two large propeners use by suc-after the Wright plan, the slip might even be prac-tically eliminated. But even then, if we should imagine the aerupiane propelled by a windlass quickly winding in a cable fastened to the top of a high mountain, thin air causes an increased consumption of power, because it makes the aeroplane lose its resistance ugainst propulsion. If it does not offer a drift of 200 pounds at 45 miles an hour it will likewise not lift 900 pounds at 45 miles an hour, and the motor must propel it so much faster that the increased speed flually creates the same drift of 200 pounds in the thinner atr. Not considering any silp of the propeller, which only makes matters still worse, the motor must now lift "by devialises" 200 pounds 88/100 instead of 76/100 miles every minute. In Germany these natural laws are now so ciently understood that a method has been found by which the maximum height an aeroplane can reach is quickly calculated from the amount of overload it was found able to carry in weight lifting tests near the ground. it so much faster that the increased speed finally creates

#### An Object Lesson in Road Maintenance

I N order to demonstrate the value of practical main-tecuance of highways, the American Highway Asso-ciation, the central good roads organization of the United States, has arranged, in co-operation with the Federal Office of Public Roads, and road officials in Virginia, North Carolina, South Carolina, and Georgia, for an ambitious maintenance experiment on the road m Washington to Atlanta, Ga. miles of road are expected to be improved and kept in condition as a result of the initiative of the American Highway Association. The experiment is on a larger scale than any maintenance experiment ever undertaken in this country.

The great maintenance object lesson road extends from the capital of the United States through historic section of the country, passing such famou points as Arlington, Mt. Vernon, the battlefields Run, Chancellorsville, Spottsylvania, and Fredericka-burg, ca route to Richmond, thence extending south-ward through the capitals of North and South Caro-

lina, and terminating at Atlanta.

The American Highway Association will enlist the support of the counties and districts traversed by the road, and, wherever possible, induce the local authoriread, and, wherever possible induce the focal author-ties to place the road under the supervision of Govern-ment engineers who will be detailed from the Office of Public Roads for that purpose under the co-operative

Probably 75 per cent of the total mileage has already been improved by a surfacing of atone, gravel or a mixture of sand and clay. The object of the main-tenance scheme is to prevent the improved portions of the road from deteriorating for lack of suitable care, and to make the unimproved portions as comfortable for travel as possible with the money available.

With the co-operation of all different communities, however, it is hoped that concerted work will be under-taken on the entire stretch of highway, resulting in a continuous maintenance object lesson that will be a silmulus to maintenance throughout the country. The American Highway Association has undertaken to raise oney for the traveling expenses of the engineer who will supervise the work,

Leonard Tufts is chairman of the committee design nated by the association to have charge of the cam-paign, and he has already arranged to place 110 miles under Government engineers. It is expected that all counties traversed by the road will cheerfully

By taking the SCIENTIFIC AMERICAN and SUPPLEMENT the subscriber receives the benefit of a re-duction in the subscription price.

#### Obitnary HENRY E. MEAD

In recording the death of Mr. Henry E. Mead among one of the oldest employees in continuous service of Munn & Co. and in connection with the SCHENTIPE AMERICAN, it is fitting to mention a few of the charamenican, a is injuring to mention a rew of the char-acteristics that were noticeable during his long career. His death came rather suddenly on the morning of November 28th, 1918, at his residence in Glenrock, New Jarsey, in his seventy-fifth year.

He was engaged by one of the original founders of the Scientific American, Mr. Alfred E. Beach, of the firm SCIENTIFIC AMBRICAN, Mr. Alfred E. Beach, of the firm of Munn & Co., in the year 1807 as a draughtenan on wood, preparing litestrations of mechanical and similar subjects thereon for the wood engraver of that period to execute. Mr. Mead had a faculty of quietly grasping the essential features of a given subject and bringing them out clearly upon the wood block, which made the resulting engraving equally clear and effective. When it is remembered that during this period, long in advance of the present day of rapid photo-engraving methods, he prepared illustrations of some of the then new discoveries or inventions like the electric light, honograph, talephone, exhibit elegraphy, and numerous new discoveries or inventions like the electric light, phonograph, telephone, cable telegraphy, and numerous mechanical inventions, it will be recognised that he covered a remarkable range of subjects. He was a mechanical artist of great care and accumer, and his work as recorded in the Scientific American will be of future historical value.

#### The Current Supplement

N this issue of the Scientific American Sufficients. Messrs. G. A. Burrel and S. N. Seibert describe and discuss the experiments carried on by our Government on the use of small animals, such as mice and canaries, to test mine gases for poisonous constituents.—Prof. E. Troussart of the French National Museum of Natural History contributes a very interesting article on the question, "Did the Horse Exist in America When This Continent was Discovered by Europeans?"—An important engineering topic discussed is that of the best limits Continent was Discovered by Europeans?"—An import-nt segiment tople discussed is that of the best limits for steam turbine units.—The recently opened Chai-tanoons hydro-electric power development is illustrated and described.—Airred E. Waller writes on dynamo-olectric lighting for automobiles.—A subject which is at the present time receiving a well-deserved interest at the present time receiving a well-deserved increast is that of asfety in industrial operations. A valuable report on an investigation of protection devices for grinding wheels forms the subject of a paper read by R. G. Williams, before the American Society of Me-chanical Engineers, and published in this week's issue. chanical Engineers, and published in this week's issue.

—F. Donaldoon writes on the sinking and linking of shafts.—There is every promise that a new industry will come to America through efforts now being made under Government anuptless to raise hyacintha, tulps and others bulbs here, Ensead of importing them, as has been the custom hitherto, from Holland. Mr. Guy E. Mitchell tells us of this development.—An automatic fire alarm whose action is based on the use of a conductor with a negative temperature co-efficient of elecductor with a negative temperature co-emcent or eser-tic resistance is described by F. A. J. Fitzgerskid—An article on Asrial Flight, by H. R. A. Mailcok among other things exposes a common fallacy regarding the use of pendium devices for stabilisting aeroplanes.

Bide-disping of Aeroplanes
To the Better of the Sciencero America:
An addition to the suggestions on "Prevention
Aviation accidents" given in my communication pu In "success" to the suggestions on "prevention of Arithm Anothers" given in my communication published in the Scinsvirso Ausman of October 4th last, it would like to offer some further ideas on this subject with especial seferance to that numerous class of espidents due to side-slipping, as I see there were three such mishaps in Birope quite recently—one of Maiden-hea, Singland, on August 20th, snother at Melica, France, on August 31st, and the third in Buckinghan shire on September 22nd—resulting in the death eroplanists and injuries to five others.

It is obvious that the tendency to side-slip is height and and maintained by the vertical surface constitu-ing the sides of the inclosed fuseinge in many late monoplanes, and in fact by all vertical surface below the monoplane's wings, as well as by any excess of vertical surface below the center of gravity in a hiplane vertical surface season the center of gravity in a update as compared with the amount above that level. The vertical surfaces inserted just below the upper plane, on each side of the middle, in the latter models of Wright seroplanes and in the Curtus airboats are presumably latended to offset the amount of lower verpresumably intended to orner the amount or lower ver-tical surface on the forward extensions and on the floats, respectively, and thus prevent the tendency to side-slip due to the latter; but it is doubtful that this is siweve sufficient.

Now, if vertical surface were provided still higher up in an aeroplane, extending above the top plane, where there is generally a king-post, anyway, in monplanes, more leverage would be exerted by the san amount of surface during side-slipping for alding in restoring the machine to an even keel. If such a per-manent vertical fin might sometimes operate to disadvantage, as in side-gusts, a horisontally-pivoted Ver vanuace, as in anequace, a principle of the first standing surface, normally open, or an extendable and restable curtain, or series of curtains, might be used instead, such surfaces being instantly convertible into a vertical fin when needed to prevent addealipping, as

in banking during turns.

An even more efficient device for preventing sideslipping, and one that could be used either alone or in conjunction with the foregoing, would consist in dihe-dral surfaces of about 45 degrees angle situated at each lateral end of the aeroplane and preferably extending both above and below the outer tips of the planes if in the form of Venetian blinds or extendable curtains, but extending only above the planes from the tips if in fixed form as dihedral surfaces; and if these latter would cause trouble in side-guests the situation could be bettered by having them normally in vertical position extending half above and half below the wing and pivoted in the middle so as to be instantly turnable, with little effort, to the 45-degree angle at both wing-tips in case of side-slip threatening or occurring.

Besides, such vertical or dihedral surfaces at the planes' lateral ends would be of value by helping to planes at the tips and thus give increased life to com-pensate for their added head resistance and weight; for flying machine designers are at last cuming to realise that this air-rarefaction on the tops of planes is a valuable contributor to lift efficiency.

Inasmuch as these vertical and dihedral surfaces need not be at all large in order to accomplish their purpose, on account of the leverage they exert, and as they could be so easily added to even existing machines, it would seem to be the part of wisdom to so equip ali aeroplanes; for it is still too true that aviato time to "make their mark in the world" in the wrong way and for the last time! Erwen G. Serry

#### Science and Education in the Future

To the Editor of the SCHENTIFIC AMBRICAN:

Allow me to note my appreciation of your editorial in the issue of November 22nd "Science and Education of the Future.

The idea for the consideration of those who follow science that the needs of men are not purely material is particularly commendable. Until science shall deal with those problems effecting the moral status of society as now provious successing the moral status of society as a whole, arising through those workings of antural law as applied to the manner in which uses should live in rejection with such other, those learnifesule conditions outsides powerty in the midst of planty will manifest themselves.

here is more poverty in stunted minds than in the stouments. Men are after meterial chings only the ties of poverty persists. Retieve them of this

fear and the desire for better things appears. Science solve the matter of right living by applying to the stion what is intended by natural law should be. All anion te is based on physical conditions as the first man found them. Is natural law so weak a thing that there is no application of it possible to what most concerns humanity? Bacon said that "we can command nature only by obeying her." Our social state teems with errors that will not stand the test of true science. We are artificial instead of natural in our manner of ng together. There are laws governing wages, re and interest; and the laws when fully comprehended will be found to determine that equitable distribution of the products of land, labor, and caultal so necessary to produce in society that which will go to make up a harmonious whole and conduce to the moral uplifting of the race.

The church has had this matter in hand too long; and has almost utterly failed. Science should assume its proper function and take hold with all the intellie at its command, and if nothing is taken for granted but what will stand the test, science will succ

Callaway, Neb. FRANK L. HAYCOCK.

#### Humane Animal Tran

To the Editor of the SCIENTIFIC AMERICAN:

I desire to thank you for the space accorded my apal for the invention of a humane animal trap to take peal for the invention of a minimum annual course the place of the cruel, torturing steel trap that causes such agony (for hours and even days) to the hapless foxes and other animals that are caught in its iron tanth, until the trapper comes along to "empty" the

The several letters published since mine appeared show that the suggestion was thoughtfully received, but the communication from Mr. Magrath in your issue of October 25th, suggesting that one of the humane societies offer a prize of \$500 through the Scientific American. for a practical humane trap that would put the anim painle saly to death without first torturing it, is the best that has appeared, and I heartly and strongly indorse that writer's most excellent suggestion and trust that those most interested will make the prize offer a positive fact, or perhaps some humane reader of the SCIENTIFIC AMERICAN would be willing to offer the \$500 prise out of his own pocket.

If I were a man of wealth I should not invite s one else to perform a duty that I (as a friend of animals) considered belonged to me, but unfortunately I am not a Henry Bergh. I am deeply grateful, how ever, to the Scientific American for what it has done in the matter. George Foster Howell.

Brooklyn, N. Y.

#### Kites for Carrying Lifelines

To the Editor of the SCIENTIFIC AMERICAN:
The convention for the furtherance of safety at sea,
which is about to be or is being held in London,
brings to my mind an idea which has haunted me for

Every time this idea has presented itself I have put it aside on the ground that it was so obvious, that it must have occurred to many minds more conversant than with the subject in question, and by them re jected as impractical. Yet, on the other hand, I have never been able to detect any serious flaws to my scheme. To come to the point: Why are not all ships science. To come to the point: why are not an anipa equipped with kites capable of taking a lifeline ashore? It would seem to me that about 90 per cent of all ship-wrecks are off a shore, and in most cases happen while a strong wind is blowing. Kites are made to-day on scientific principles with very great steadiness and much I fail to see why a kite should able to carry ashore to leeward as large a cord as can be shot from a gun to some one, and with greater surety and over a greater distance. The shore is a large mark and the ship a small one.

Of course I have not marked out the details. Wheth

the kite should be "box" or otherwise; whether it should carry the cord as a fall or be equipped with a tripping device to cause it to collapse at the proper moment; these are questions to be decided by experi-ment, but which would appear to present trifling mechanical difficulties.

Kites are cheap and they are easily stowed Indian Mill, South Natick, Mass. John JOHN BOTT

#### A Suggestion for Life Saving

To the Editor of the SCIENTIFIC AMERICAN:

To be some or the schemers and idea which has suggested itself to me in connection with saving life at sea in that particular condition which provents the use of bosts owing to herrific seas.

I base my idea on the assumption that the man-lift-

ing kite as used occasionally in military work for ob vation purposes is a practical idea. I propose that the vessel which is rendering help should on approaching

the sinking or disabled vessel run out a man-lifting kite the sanking or dissolved vessel; run out a man-irring site. She would maneuver to windward so as to bring the line over the distressed vessel. Then following the idea which boys make use of in sending a "message" along the line, an encloses trailing light rope would be dispatched. This would run one pulley with a wind sheet The gale, or strong wind, would send this along, and as the trailer passed over the ship in distress it would be seized. The line could now be hauled down to the deck of the distressed ship and a breeches bliog with pulley could be placed in position on the main line. Then when everything was ready the trailing line would be eased out and the pull of the main line would lift the breeches buoy with its human freight into mid-As soon as it reached a certain altitude a releasing device would allow it to run toward the rescue ship. Gravity effects this, the pulley and breeches buoy running down the inclined plane. Rescue in a gale of wind and mountainous seas could thus be effected, while the use of boats is out of the question

The declivity of the inclined plane represented by the line could be regulated by the trailing rope. On easing the tralling rope out, the main kite line would rise; on haufing it in, the kite line would be brought lower. this way the inclined plane between the two ships could ntrolled and the speed of the breeches buoy and its freight governed

I have not patented the idea, preferring to place it t fore the SCIENTIFIC AMERICAN.

If you think there is a possibility of the idea being developed, you are welcome to make use of my suggestion.

R. Macdonald. Leicestershire Club, Leicester, England.

## Studying Ripening Bananas With the Respiration Calorimeter

ESSRS. C. F. LANGWORTHY and R D Milner MESSIES. C. F. LANGWORTHY and R. D. Milner of the Department of Agriculture, have published in a special bulletin, some results obtained in studying ripening bananas with the respiration calorimeter.

deration of the available experimental other data obtained shows that the successful handling of fruit during transportation, in the cold-storage ware house, and in the home depends upon a knowledge of nouns, and in the lome depends upon a gnowledge of the changes which take place in ripening, after ripen-ing, and decay, and the causes of these changes and ways in which they may be controlled 'tresent prac-tice is based on knowledge gained by experience, supplemented by work curried on in the inboratory.

The respiration calorimeter offers a new means for

atudying fruit-ripening problems. The results with bananas during the active ripening period show that the ripening changes progress regularly to a maximum and then decline; that at its greatest intensity the heat produced is equivalent to approximately one calorie per hour per kilogramme of bananas. The heat illier is a measure of the activity of one or more of the ripening processes. Analysis has shown that during ripening the banana starch is transformed into came sugar and the cane sugar into invert sugar, and that there are important changes in the character of the taunin comby the production of aroma and flavor bodies, and perhaps in other ways. It has also been found that in on to the transformation of carbohydrates there is an actual loss of this food constituent during ripen-From the data for oxygen consumption, dioxide, and heat output it appears that the heat liberdated by the ripouling banamas is due largely to the destruction of curbohydrate. The results recorded and discussed represent only a part of the material which is being accumulated. No attempt is made to draw is being accumulated. So arrespond in made to draw deductions regarding the practical applications which can be made, as this may be done more properly when experiments now under way are completed.

#### Sixteen Miles of Rough Sea in a Canoe

R. A. G. HEBGEN of San Francisco, Cal., has M. R. A. G. HEBGEN of San Francisco, San Must completed a most remarkable trip in a motor driven cance. Although the sea was very rough, Mr. His objective point at Alameda was the meds, Cal. 1118 Cojective pools.

Encinal Boat Club House, sixteen miles from Belvedere His canoe was equipped with a rowboat motor, and in ante of the waves and general rough weather which he encountered during the entire sixteen-mile trip he made the trip in a few minutes over one bour, maintaining an average speed in his motor-driven cance of thirteen miles and forty-six yards per hour. This is one of the few instances when a very severe trial has been given to the motor, and it is interesting to note that, in suite of conditions which were not of the best, Mr. Hebgen maintained an even speed from the time he left Belve-dere until he reached his objective point many miles When Mr. Hebgen passed over the water bay he crossed Raccoon Strait on his way around Yerbs

## Atlantic Steamships—A Retrospect

#### Thirteen Years' Development of the Transatlantic Liner

By J. Bernard Walker

In the autumn of the year 1900, that is to say, just 13 years ago, the NEISTIFIC AMERICAN published an article dealing with the question of the possible increase in size and speed of the fast transatiantle timer. That was the year when the old "Deutschind," now the reconstructed "Victoria Luise" of the Hamburg-American tracked "Victoria Luise" of the Hamburg-Americant Control of the Control of

on the Atlantic Ocean exist only in the inantination of the passengers; but in this case the cowners, stung by the assertion of the rival line that the "Deutschland' could not have made 23 knots on her madeu trip, deliberately skarted the ship just one hour later than the "Kaiser Wilbeim dee Grosse," which was overtaken and passed about non of the following day, and the superiority of pased of about one knot of the new ship thereby established beyond question. The enthusiasm belief the passenger of the "Deutschland" led to the the speed of the "Deutschland" led to the speed of the speed of the "Deutschland" led to the speed of the speed o

With a view to making an approximate estimate of the dimensions and horse-jow-er which would be necessary to enable a consistency of the Theutschland' type to cross the Arlantic at an average speed of 30 knots, the writer made some rough calculations and embodied the results in a drawing, published in our laste of November 10th, 1900, which is herewith reproduced. It was disclosed that a four-day, thirty-knot vessel, equipped with motive power consisting of Scotch bollers and reciprocating engines, and bulk within the limits of draught of thirty-free imposed by the German harbors of that day, would have to be 190 feet long and 87 feet broad; that it would displace 40,000 tons; and that the horse-power required would be

In view of the fact that during the intervening years, since the article was written, the during suggestions as to growth in size and speed have been surpassed, the former by the "Imperator" and the "Vateriand," and the latter by at least one of the large British battle-Cribers, we republish on the accomnaulying page the original drawings and make the following quotation from the text of the article, as published in 1900;

"Four-Day Liver.—As to the possibilities of the future, it is ordient that with our present form of futil and type of motive power, we have present form of futil and type of motive power, we have been present formed at 30 knots would require about \$8,00 to Deutschland at 30 knots would require about \$8,00 to Deutschland at 30 knots would require about \$8,00 to Deutschland at 30 knot Deutschland at 30 knot Deutschland, it would be impressed as 300-knot Deutschland, it would be impressed to put into her shell more than one half of the necessary amount of power. Evidently to secure 50 knots a tarper boat would be required, and a larger boat monite his creased power to drive the increased weight. The increased power to drive the increased weight. The increase in power, however, would not be directly proportional to the increase in the displacement, the tourer ship being ton for ton easier to drive, because of the reflectment of her lines due to her greater length. Newartheless, by the time we have designed a boat large enough to carry the power corresponding to a speed of 30 knots, we shall have upon paper the mammoth ship represented in our drawings. She will be 380 feet over all, 87 feet in beam, and 30 feet in draught, and will displace about 40,000 tons. Engines of 110,000 horsepower would be required, and even fit tiple screws were used, it would she necessary to develop 37,000 horse

power on each shaft—a task that would stagger the best of the world's engine builders of to-day. Profifour double-ended Secute builders would be required to supply the steam, and during each day's run of twestyfour hours 1/10 tons of coal coating 87,100 would have to be fed into the 352 turnaces. It would require 7,200 tons of coal to carry the vesset to Plymouth and 8,500 tons to take her to Hamburg, the cost of the fusi closs being \$80,000. The ship would have to stow 9,500 tons of coat in her bunkers for a single trip across the Atlantic.

"To anyone who has watched the reverse bending strains to which a ship like the "Destachland' is subjected whom she is being driven across the Atlantic seas, it is evident that we have come to a point where it will be necessary to give increased longitudinal strength to any vessel that acceeds the present length

The bow of this ship (the "Imperator") reaches 56 feet above the sea; the captain's bridge is 75 feet above the same level.

The towering topsides of a modern liner

of 700 feet in a four-day liner this might be prosided for by running a longitudinal stiffened builkined, catending from the keet to the promenade deck, through the vessel between the after enther-room and the forward boiler-room builkined. The vessel might be further strendthened by carrying up the side plating to the promenade deck, which is placed one deck higher than in the Deutschland, and by doubling the plating at the blikes and at the promenade deck, as shown in the middling bection of the ship.

"In conclusion, it is safe to say that such a vessel as

this will nower be built. We shall come the atlant in four days, but not with a vessel of this type. We higher speed will be attributed, nor for statisficiality ended and boilers weights, but ratther by mentiophing reason and boilers weights, but ratther by mentiophing reasons and coming speed, and utilities, owner profits and coming speed, and utilities, owner profits of the way of economisters, superheaters and tisel-twiner least the "Arrow," described in our last sense of the times at the "Arrow," described in our last sense of the times at appearance within the next flow years, it is suffer by all the state of the sense of the Parsons type. So gives will be fine duction of weights and stury of appearance, the sense of t

to produce on a displacement not much greater than
that of the 'Destactions' a 80-knot occur
steamer that shall have aqual accommodations for passengers.

to the commondations of the commondations for passengers."

It is interesting to note, after the lague of thirtsee years, to what extent the prediction of 1900 has been fulfilled in 1913, in the first place we find that, in order to give the proper girder strength, the doubling of the plating has been incorporated in the present-day ships of 600 to 900 fact length. The "Maurenain" has three-fold plating 3 inches in aggregate thickness for some 800 feet amodality, a special steel of high tensile strength being used. The "Muperator" has double plating, and in both of these ships the girder strength is further assured by constructing the main and other upper desits of steel such by a great increases in the plated depth of the ship. The "Maurenaina" is plicted to a depth of sixty-one first, and the "Imperator" to a depth of seventy-three and one half feet. The smociation of steel decks and doubled plating with great depth of ship sakes it unnecessary to use the central longitudinal builthead which would have been necessary in our four-day boat with its relatively shallow plated depth of about fifty-two feet, shallow plated depth of about fifty-two feet,

More striking, even, than the increase in length is the great beight to which the structure of the modern liner has reached—a fact which is clearly shown in the shadow picture at the bottom of the accompanying nace, in which it will be sens that the topmost deck of the "Imperator" is level with the tops of the amotestacks of the "Deutschland." The "Imperator has no less than eight decks above the waterline, as against four in the "Deutschland." From the waterline, as against four in the "Deutschland." From lead to the varieties, as against four in the "Deutschland." From less the waterline, as against four in the "Deutschland." From less the waterline, as against four in the "Deutschland." From less thought the waterline, as against four in the "Deutschland." From less thought the waterline, as against four in the "Deutschland." From less than the waterline waterl

But the "imperator," on a draught of 37 set and a beam of 98 feet, has ample stability to carry her towering superstructures. In 1800 the steam turbine was yet, in so far as occan steamers were concerned, in the experimental stage; and, as we showed at the time, the three triple-expension estimes for a four-day "Destrehland" would have reached a size for-sacto unit of \$3,000 home-power. We queedlon whether the steel gaskers of that or of this day, for that matter, would have chard to gaurantie hollow-forged sharting to carry safety a load of this magnitude.

The first notable step toward the 30-knot limit was

## How Many Stars Are There in the Milky Way?

#### A Great Astronomical Problem and How It Is Attacked

By John W. N. Sullivan

ted With Photographs Made at the Yerkes Observatory

O N a clear monthess night, if the sky be attentively observed, a dim, broad, freeguier patch of light may be seen, sweeping right across the heavens from horizon. This long and featily lumihous cloud is known as the Miky Way, and it does in truth make a complete circuit of the heavens. If observation is assisted by a powerful tolescope this hand of luminous have leaven to countiest of accounted multitude of states.

haze is seen to consist of a countless multitude of stars.

It would seem that any attempt to calculate the properties of a system of such exceeding complexity must be fore-doomed to fullure. Nevertheless, it is possible, by mathematical reasoning, to reach certain conclusions respecting the constitution of this object which are of the highest interest and importance. The mathematical methods necessary for such an undertaking have been developed by Maxwell, in connection with his researches on the theory of gases. A gas is regarded as made up of an immense number of very small particles, moving about in various directions and with various velocities. se small particles act on one another at a distance but in such a manner that at a distance large compared with their own dimensions, their mutual action is inappreciable. But if two such particles come sufficiently close together, they perturb each other's motion, and the result is a different distribution of velocity. The fact that the particles are present in enormous numbers and that their motions are random ones, renders the application of the theory of probabilities possible, and on this basis many of the characteristic properties of gases have been satisfactorily explained.

Lord Kelvin, by a bold imaginative leap, jumped from the consideration of a gas to the Milky Way. There also we have an immonspunumber of bodies moving at random, perturbing one another's motions at short distances and exerting no appreciable effect at large ones. To the mind of some super-human being, to whom the stars of the heavens appear as molecules do to us, the Milky Way is but a gas, free in space. The statistical methods of calculation introduced by Maxwell may be used in this case also. Among other things, we are in a position to calculate the dimensions of the Milky Way, from observations on the velocities of the stars

It is asswer resorved from its containing reseal and forf. free in space, it would, under the action of the nutral attraction of its particles, assume the form of a sphere. At the center of such a sphere the pressure, the nutral attraction is a sphere at the pressure, the center throughout the substantiant of the particles, and the pressure, the nutral transition of the sphere and the sphere attraction of the sphere and that the kinetic pherical particles and compatible with the hypothesis of a homeopascous of compatible with the hypothesis of a homeopascous

sphere.
This theoretical result, that there are one billion stars in the Milky Way, is the same as has been reached by telescopic observation, a fact which is distinctly sur-

Action in the

prising. For the theoretical result gives the total sunber of stars present, while telescopic observation can only give the number of bright stars present. From the concordance of the two results it would appear either that there are no dark stars in the Milky Way, or that their number is altogether inappreciable in comparison with the bright stars. We shall see that this result is rather disconcerting when considering the age of the Milky Wer.

In rearrding the Milky Way as a gas we have not been sufficiently precise in our conceptions. Everybody is now familiar with the fact that Crookes discorrend the existence of a fourth state of matter; matter which is notifier sold nor liquid har gaineau, and which has been named radiant matter. The difference between radiant matters and a gas is quite easy to green? If it is a vessel contacting particles of matter is matched the chances are that a particle, in traversing the vessel, will appear one on or more conflictions with other particles, then such an assemblage of particles is existed as an If it is possible for the particle to revenue the vessel without collision, the nature is said to be good and, so that an assemblage of particles which is, one vessel is a gas may, in a washer vessel, he is the reference and the control of the place is a state of the particle of the particles and the real case. It is not so made to the place is a state of the control of the place is particles, which is the paper including the corts of the places is provided only over one extravel and the particles are a fact to now therefore the particles are a fact to now the particles a

The spiral nebula Messier 51 in Canes Venatici. The Milky Way may be such a spiral nebula.

a fatal issue may be expected. Lastly, the days of rapid, rough-and-ready military surgery—of bullet ax-intenset and limbs amputated on the battlefeld—are gone by Modern surgery, with its audacity of scope and ultra-reliancement of method, demands too great attention to details, too perfect a quiet in its curricularies, and too build the for operating, to permit of the days o

leging practiced amplitude of battle.

"Br. Helms is of the opision, at the same time, that our generation, with its over-stimulated and over-outivated nervous system, is quite incapable of enduring the pain and nervous shocks through which the property of the proposers of Nanoleon's armine managed to He.

sards of Napoleon's armise managed to live.

The actual course of events with the wounded solder is thus dramatically detailed. With eyes fixed stright in from sot him, and filled with the warlike intoxication which eliminates the instinct of self-preservation, the soldier follows the orders of his leaders until he feels himself hit. Then another instinct than the ardor of bettle takes possession of his whole being; he now thinks of nothing but finding his way to the wretched company of the stricken, to share his sufferings with them. In this way there are formed on the field of battle what General Trousshit (the surgeon-in-chief of the Franch army) calls "nests of wounded," Here the

medical students and young doctors have congregated in the mids of the troops, provided with morphise to hill pain, caffeine to stimulate the heart, and servan to repair the tissues wasted by loss of blood. The three great dangers to be met in these early stages of the case are asphyria, hemorrhage, and infection. Against the last of these three the French soldier is fortified by a little peckage which he is obliged to carry with him as part of his require field kit. Within its outer covering of gray lines this package contains another, an impermental envelop, and inside this again is a provision of aseptic lint covered with fine gauze, besides a large bandase and two safety pins. Outside is a label on which are printed explicit directions for the use of this first-aid (or panament unitedieds) apparatus. If the soldier is wise and provident, he will have throughly mastered these printed instructions long before the necessity for applying them arrives; if he is only the average human recruit, and has never looked at them until his hour of anguish arrives, he ought even then to be able to understand their large, heavy type and simple precision of lancings.

The next thing for the victim to de will be to take

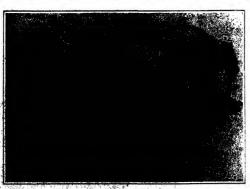

The next thing for the victim to do will be to take advantage of the first tuil in the fighting to drag thin-self to the nearest medical post, or "nest of assistance," which ought to be 1,050 meters (4,921 feet) or 2,000 meters (6,922 feet) to the rear of the titing time. Here his wounds will receive heir first selecutific dressing with antiseptics. At the same time the case is diagnosed, and a ticket is pinned on to his cond—are deticket, if he is to be removed to the base hospital, a white one, if he is to be left where he is. In the former case, he will be carried off on a scientificatily constructed stretcher (breacourt), the Freuch type of which is the Eybert, a countrience as constructed as to be available for transporting the wounded man either in a wagon, on the back of a music or on the back of a hospital orderly. For the last of these means of transportation, the brascerf is strapped, nearly upright, to the force beed, shoulders and hips of the bearer, so that the patient may keep the sitting and slightly prone position desirable in cases of abdominal lesions and known as "Fowlers" position."

So much for the routine of gleaning the human harvest while and where the buttie will raps. When the turnell and acute danger lave shifted elsewhere, it is possible for the ambitances to make their rounds and pick up the wounded. The modern army ambulance (these are stricted to every French erany corps) is a field heaptal on wheels, equipped with facilities for immediate transment of cases in which delay would estail serious danger. The "field heaptal" of thirty years ago is now only a memory. The ambitance, an automobie, takes its load as quickly and with as little diding a possible to the base hospital, where the veteran surgeons, Red Cross nurses, and all the healing resources of modern science are to be found, and quickly and orderly conditions almost as favorable to the pattern

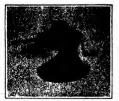

ages bearing the red cross or regengines bearing the red cross or regengine to "To return to the attifield, the work of the surgeons and their orderites does not call with day. At night they have to secur the country and gather in wounded men who have been unable to find the description of the surgeon of course, provided with lanterna and in this connection Dr. Helme describes the Gresard Berther light, which is specially constructed for the service of the wounded in war. It is an acceptable light, provided with a reflector, which brilliantly illuminates the ground within a radius of 8 meters (20% feet), but a guite imperceptible beyond 400 meters (1.512 feet) — as fe distance, considering that insolt surgeon within anything like so short a ranges now-adoys never encomp within anything like so short a range.

In this work the traditional friend of man, the dog tribe, also takes parl, represented by that German development the Santitatahusd and his Franch version, the chien antitaire. The method of the German Santitishund is simply to find a wounded man and then bay over

ed man and then bay (Concluded on page 481.)

My 1.—The division of weight necessing to location shown in the human body. The 3.—Constitution for transporting wounded man on the book of a hospital weighty. The 3.—Satisful of carrying the wounded on mule back.

## Inventions New and Interesting

Simple Patent Law; Patent Office News; Notes on Trademarks

Another interior view of the side-ent-ter sharpener.

Pencil Sharpeners

A LARGE number of mechanical devices for replac
ins, the penkulfs in removing the wood and point
ing the lead of the ordinary lead pencil have been invented. It takes a keen knife and no little skill to nivenired it takes a keen kinte and no little skill for sharpen a lead pencil quickly and without waste and yet nearly eversone likes to have it neatly treated hence the legion of pencil sharpeners ranging from the little cone sharped pocket device of boyhood days with a fixed blads for shaving off wood and lead when the sharpener was twisted about on the end of the pencil to the well-designed machine for serious, con nuous business use
The usefulness of a lead pencii is practically hindered

The usefulness of a lead pencil is practically hindered by the fact that not everyone can keep a possell sharp-ened simply because not everyone knows how to handle a peakerife Moreover cutting the graphite lead" dulls a good knife blade rapidly. The section of the pape-pencil (in which a fresh length of lead is exposed by simply slitting the pencil and uncurring a strip of paper) avoids this operation where a sharp point is not necessary. Where many pencils are used as in

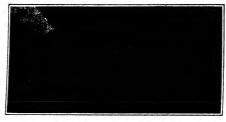

schools, offices telephone exchanges, some quicker of more efficient means of keeping the pencils in good edition than by the hand whitting method become

imperative.

The ideal device for this purpose should i The total device for this purpose should first of all aver time, as compared with moderate skill by the primitive method. The auditor of a large railway system an enthusastic uses of pencil sharpeners for his 120 clerks, somewhat humorously estimates the saving of time on each pencil sa 10 minutes, divided as follows Borrowing neighbors knife, 2 minutes, sharpen-

Il starpener should also
possible, not only in the
p work, but in protecting
section. It should waste
at saids shoupening, and fitted: powed adaptement should also minimised by demittin, seed only in the 11 shirepening work, yet in protecting point from benefits. It should wash out from benefits, the protecting of the least at shoul shirepening, and other benefit in long use for the penalt, hought do distinctively, next work while thing the delling of positives and do y with the litter which noing a knife anses. If these sequirements are acti-actority fulfilled the device may still be sulty through its tendency to break the In the hand-whittling method, given keen peakuife, special skill in sharpen-ig a lead pencil is required to point the ad after the wood has been whittled ay. The expert human pencil sharpener porting the exposed length of the lead the ball of his finger to ease the chut-ering pressure of the knife edge. It is say that scheming to deal with this ate operation has been the main probtem in the majority of pencii sharpening ces that have been invented.

In this connection it is noteworthy that many pencil sharpeners which will give good results when new, will break the pencil point by the looseness or side mo-tion of the cutting tool when the bearings of the machine become worn; and the bearings of a pencii sharpener are particularly liable to become worn by foul-ing with the gritty pencil lead litter in the of the m

ering some of the repres tive pencil sharpeners it is interesting to divide them into two broad cleaners. ing to whether the device works by a spe od, or like a sort of automaton penknife neer. Many machines for use rming a given work are not imits tive of the primitive hand labor operation which they are designed to supersede, but have a new and special way of doing the work. For example, the ordinary so machine does not pass a common h wife's needle completely through the fabric on which it is working, but utilises a spe-cial needle, with its eye in the point, which it stabs in and out of the fabric. Just so the majority of the pencil share-Just so the majority of the pencii shari-eners which have seen the light of actual use remove the wood and point the lead in a way of their own, and not by an imitation of hard whittling.

Perhaps the unjority of pencil sharpeners of both these classes are little machines arranged to be fastened to the wall or to a table and having a crank and One popular type which does the by a method wholly different from work by a m hand whittling has a rair of small bevoled milling cutters which while rotating indi vidually revolve as a pair about the pencil ng away first the wood and late the lead as the pencil is fed through s clamping support in the axis of revolution of the cutters. One object of this design with two cutters bearing against the pe point from opposite sides is to relieve th exposed length of lead from the side strain which is so liable to break it. Several other sharpeners of this type, however have a single cutter driven from a gear wheel and cutting from one side of the only, the pencil being gradually turned as the work proceeds. In some of machines the pencii is hold in a simple friction clamp in which the operator turns the pencil about; in others, the satically rotated. A recen nachine of this type utilises the milling with a spiral cutter having 15 inches of cutting edge, designed to make a ood point without strain on the lead. The encil point is supported against a straigh edge while this cutter is at work on it, and the last gives an extreme 'draw out."

Another machine, an evolution from the schoolbay's toy which has been referred schooling's toy which has been referred to, is designed to protect the wood-cutting blade from being fulled by work on the puttil lead. Turning the creak rotates the pentil lead's Turning the creak rotates the pentil lead's rapidly against a station-say lead's rapidly against a station-say lead's plade which takes off a thin sightly shaving from the wood of the pentil until second of the pentil s

aive tool then the interest to a po of them coming into play to grind

Several forms of sharpeners which freakly indicate whittling have a disk carrying several sharp knife blades ar-ranged radially which rapidly sliver the wood of the vertically held pencil as the disk is rotated. Slowly turning the pencil about and at the same time feeding it downward in its clamp closely simulate the action of a penknife in skilled hands One representative of this type has the knives arranged to draw out the pencil point. Another handy little desk device, weighing less than three quarters of a pound, sharpens pencils by a reciprocating motion of a single adjustable blade carried on a rocking arm. The pencii is laid against a support in a slanting posi-tion and the blade is brought into action by a downward push instead of by the turning of a crank, so that the d does not need to be fastened to any sup port, but may serve also as a paper w The base is cup-shaped to catch the penci cuttings, and stands on three rubber-tippe feet. This same chisel motion of a blad is utilized in another compact sharpener equipped with a vertical plunger like a dating or numbering stamp. The blade has 4 inches of cutting edge and it is kept in condition automatically by a sharpen ing stone, which is held against the b by spring pressure. In this connection mention should be made of the little per cil sharpeners which may be found in som stationery stores—an attractive miniatur jack plane for the desk or pocket.

#### An Efficient Air Deflector

AN apparatus for changing the direction of a current of air with the minimum loss in the velocity of the same has been recently designed and patented by H. L. Van Zile of New York city.

iple involved is sh The prine mpanying illustration.

An efficient air deflector.

In this deflector a series of curved va in this deflector a series of curved vane are placed at equal distances from each other, presenting their edges to the cur-rent, and dividing the same into indepen-dent strata. Each independent portion rent, and dividing the same into indepen-dent strata. Each independent portion implages against a vane, and after being slightly deflected proceeds to the end of the protected passage without further loss of energy due to any impingement of the balance of the current. The cherry actually lost, neglecting sich-friction, is due to the impingament of the stratagainst the lower portions of the vasas. As application of the above principle is made for windows. With this device the wind is addasted to a vertical oursety inside of the room with a loss of only 18.3 per cent of its velocity. The enemy of this vertical oursets in stiffledent to deflort as horizontal current is stiffledent to deflort as horizontal current entering the window over the deflector, the amount of such deflection and the resulting direction being degendent on the relative strength of the two currents. It is, therefore, possible to have the lower sain raised above the

deflector and still have the incoming air traveling to the upper portion of the room without disturbing papers on deaks or without disturbing papers on deaks or tables. This feature, unique for this deflector, is very important during the During winter the sask can be adjusted to admit only the amount of air desired, and as this air will travel vertically at 87.7 per cent of the velocity of the outside wind, it will mix with the sated air at the top of the room instead of producing cold currents at the lower

Recent investigations by well-known ow that the movement of air in a closed room is almost as important in a closed room is almost as important as the entrance of fresh air. This deflector accomplishes both results with the mini-mum amount of cold air owing to the high velocity of entrance.

#### A New Idea in Ink Erasers

NK erasers need improvement. Knive out and acrapers roughen the surface of paper; rubber mixed with powdered gla or sand wears through and is apt to tear the paper, white chemicals discolor the paper and obliterate ruled lines, as well as the letters or figures they are applied to. A Syracuse inventor, Mr. J. K. Rush, eds on a different principle and

The eraser he perfected consists of a The eraser he perfected consists of a brush made of especially prepared mineral fibers and containing no less than 4,000 strands each. As the brush is only one eighth of an inch thick and three eighths of an inch wide, it will be understood that h of the 4,000 strands of fiber is ex ecedingly tenuous; but they give to each brush just 4,000 microscopic, dlamond-like points of peculiar sharpness, and together hey form an erasing edge that is flexible durable and extremely efficient. brushes are not made of asbestos or min ol, but of a substance more like spun

Each brush is two inches long and is contained in a tube of aluminium and German silver that is three and three quarters inches long and three eighths of an inch in diameter; turning a German silver cap on the end of the tube moves the

rush in or out, as required. Especially well adapted is the new moving single written or typed letter figures from a line or column neatly and without affecting the adjoining marks, and it leaves the place of the letter or figure fit for use again without danger of blurring

#### The Death of William Deering

N the death of William Deerlug, one of the founders of the International Harvester Company, and himself long the head of the Deering Harvester Company, the American machinery industry loses one of its most conspicuous figures.

Originally a dry goods manufacturer and merchant, Mr. Deering eventually migrated to Chicago, where in 1870 he met E. H. Gammon, who had bought the rights to manufacture a harvester Three years to manufacture a narvester. Three years later Mr. Deering became the active head of the enterprise. Gammon told Deering that a machine was needed which would bind sheaves of wheat as they were cut. Deering began work upon this, and with J. S. Appleby invented the binder that is etill in use. He is said to have left a furture of \$30,000,000, most of which was made out of agricultural inventions.

Deering is one of the men to whom America should be grateful for his nehlevements. It was his self-binder that made it really possible to harvest wheat without the aid of much manual labor and that places the name of Deering beside that of McCormick. How much the Deering binder has contributed to our agricultural prosperity no one can even guess

A Worm That Operates Car Coupling Kauckie er Heek.—Joseph Kovace of Kulpment, Pa., in patent No. 1,073,352 provides a segmental coupling member movable in an aro in the draw-head and on its otter also a worm gen menhed by an operating worm journaled in draw-head.

#### Notes for Inventors

Dr. B. W. Pond Resigns After Forty Years as Examiner.—Because of ill health, Dr. B. W. Pond has resigned after forty years' service in the examining corps of the Patent Office. President Wilson sent a letter to Dr. Pond thanking him his many years of service, and compli-menting him on the record he has made while in office. Dr. Pond was in charge of a very important division of the office. in which he looked after all inventions affecting cavil engancering, bridge building, hydraulto engineering, and excava-tiou. He is a native of Maine, and was graduated from Bowdoin College. He entered the Patent Office as third assistant examiner in 1873, and four years later was made primary examiner, which pos-tion he has filled for thirty-av years.

An Elihu Thomson Patent, -Putent No. 1,072,530 has been issued to the General Electric Company as assignee of Elihu Thomson for an electric heater in which a heat storage mass having good conduc-tivity constitutes a wall of a heating er, while heat manlating means con stitute the remaining walls of the said er and means are provided for producing an electric are within the chamber for heating the storage mass.

Nine Car Truck Patents,-Herbert H. Hewitt of Buffalo, N. Y, has secured mue patents, Nos. 1,072,719 to 1,072,727 in-clusive, for improvements in car trucks including improvements in the car axle journal boxes proper.

An Advertising Ventilator.-Robert E. Carswell of Minneapolis, Minn., provides in patent 1,072,821 a combined ventilator and advertising device in which there is produced upon a suitable surface a repreentation of an automobile with the wi having passages alined with them and the wheels rotatable and having, in their spoke zones, propelling lilades so that the wheels will be rotated by a draft of air moving through the air passages alined with the whoels.

A Number of Dental Patents.—Frank H. Skinner of Chicago, Ill., has secured patents Nos. 1,072,517 to 1,072,521 inclusive for various forms of crown pin extractors including jaws for gripping the pin and means co-operating with the jaws for pulling the pin.

A Shiftable Individual Telephone Mouth Piece.—In patent No 1,072,537 Clarence S. Warren of Milford, Olno, shows a telephone mouth piece which has a band to fit around a telephone transmitter and a number of individual telephone mouth pieces carried on arms pivoted to the hand so that each individual month niece may be applied to and removed from the shone mouth piece as desired.

A New Patent Office Mail Order .new Commissioner of Patents, under date of September 5th, 1913, has given notice to those transacting business with the Patent Office that all mail matter arriving raten vince that in man matter arriving at the Washington post office up to the hour of closing business at the Patent Office each day will be entered as received on that day—Iu carrying out this, suntable arrangements have been made by the local post office.

Another Reinforced Cement Tle .- In patent No. 1,071,291 Lonis Blessing of Jackson, Mich., shows a railroad tie of coment in which is embedded a longitudinal tension rod bent to have lower portions directly beneath the rails and its intermediate portion bent upwardly to form a truss inidway between the ends of the tie Milk Drying Process.—A patent No. 1,071,692 to Powdered Milk Company of

I,071,582 to Powdered Milk Company of America of New York city, assignee of Charles H. Brigham of Brooklyn, N. Y., presents a process which converts the liquid into a spray and causes a large amount of drying agent in the form of an envelope of forcibly projected air intro-duced under pressure moving in the same direction as the spray and traveling around it in such a manner as to present at each point on the path of the spray successive quantities of the drying agen

The performance of the object confesion is more claborate und, characteristically, some-what more spectacular; he obtains possessuch more specialist; in dutains possession of the patient's bat, or helt, or anything that can be runninged out of his pockets, and, carrying this as evidence, first reports to the surgeon and then leads

the way back to the sufferer.

the way back to the sufferer.

Military surgery has now made an
elaborate classification of wounds with
respect to their danger and difficulty of
treitment. For a gueral idea, however,
the accompanying diagram is sufficient,
dividing the wounds according to their dividing the wounds according to their location in the human body, into slight, serious and very serious. This diagram is reproduced from Forgases "Traité de Fathologie Externe." A statistical calculation made by one of the leading surgical authorities of the French gives the reissurgical control of the French gives the reissurgical c tive frequency of wounds not instantan sortal as : slight, 60 per cent ; seri ous, 15 per cent; very serious, 25 per cent. On the whole, the experience of recent wars shows the head and the right arm as the most frequent lodging places of

projectiles.

The greatest difficulty of modern military surgery seems to be in abdominal wounds. Their healing depends on the early application of treatment and on the feasibility of keeping the patient quiet for a, long period. Wounds of this type wrought great havoc in the battle of Spion Kop, where the wounded had to be con veyed down a rocky cliff before undergo regret town a rocky clin terore undergo-ing operation. On the other hand, a large number of Russian soldiers suffering from abdominal wounds at Mukden were successfully treated, with laparotomy, by the skill and admirably organized resources of

#### Atlantic Steamships.

(Concluded from page 473.)
the increase in the motive power, coupled
with this reduction in passenger-carrying
capacity, would render the ship an altogether unprofitable venture for the com

As regards the possibilities of the future it is certain that any of the leading ship-building firms would undertake to build anteed speed of 30 knots. But to guaran-tee that she would be prefitable is alto-gether another question; for it is well understood among shipping men, that, were it not for the very liberal assistance rendered by the British government, in the loan of the capital for construction at the low rate of 2% per cent, and in the payment of an annual subsidy for the "Mauretania" and "Lusitania" of \$750,000

Nevartheeses, we are or one opinion that would be possible, even without government assistance, and by a considerable increase in the passenger rates, to build a So-knot ship which would yield a fair revenue to its owners. The hope for this, at least so far as the operating expenses are concerned, lies in the great promise afforded by the new helical reduction gear, anorest of the new helical reduction gent, Judging from what the battle-cruisers have dene with a straight turbine drive, it is worth consideration whether the re-duction in the weight of engines and boiler plant, due to the use of reduction gear, and plant, due to the use of reduction gent, and the great swing in the coal idli due to the lighes economy of fast-running tur-blese consisted with slow-running propel-iers, would not make it possible to set affost a 50-knot liner, carrying first cablu-passenger only, and whether such a slig-in these days of multiplied wealth, would not attract unfollent first-class passengers, at high sates to make the vayages possib-

## The Telephone Doors of the Nation

WHEN you lift the Bell Telephone receiver from the hook, the doors of the nation open for you.

Wherever you may be, a multitude is within reach of your voice. As easily as you talk across the room, you can send your thoughts and words, through the open doors of Bell Service, into near-by and far-off states and communities.

At any hour of the day or night you can talk instantly, directly with whom you choose, one mile, or a hundred, or two thousand miles away.

This is possible because 7,500,000 telephones, in every part of our country, are connected and work together in the Bell System to promote the interests of the people within the community and beyond its limits.

It is the duty of the Bell System to make its service universal, giving to everyone the same privilege of talking anywhere at any time.

Because as the facilities for direct communication are extended, the people of our country are drawn closer together, and national welfare and contentment are promoted.

## THE FORWARD LOOKING WEEKLY MAGAZINE

Since the Independent appeared in its new form, with its broadened editorial appeal, the public has had an opportunity to see what the publishers meant when they said in amouncing their policy:

"The Independent will, in its new form, be the forward-looking weekly magazine-it's face to the future, its articles and pictures dealing with the affairs of today and tomorrow, its topics those in which the new generation is vitally interested.'

The Editors are concerned with live issues, with new achievements. They are anticipating this week what you are going to be thinking about next week.

#### **OUR INTERNATIONAL FUTURE** WILLIAM HOWARD TAFT

Ex-President of the United States, will contribute to early issues of the Independent a series of four articles dealing with the Monroe Doctrine and other great national problems which must be solved by the United States in the near future.

#### WHAT'S AHEAD FOR BUSINESS?

Beginning with the issue of December 25 the Independent will publish a series of srticles in which Independent with photosis a series of strates in windle leading men who know financial, manufacturing, and merchandising conditions from the inside will tell us what in their opinion the year 1914 holds in store for business.

A postal card sent to The Independent, 119 West Fortieth Street, New York, bring to you a supply of the Sixty-fifth Birthday Stamps, enabling you and friends to get acquainted with The Independent on especially favorable to

The Ritior is always glid to receive to extraminous dibituded articles on solucits of timely orients. If the photographe as solution the articles one and the fine south-orbit is contributions will receive spound attention. Accepted articles will be post for all regular space rates.

The purpose of this journal is to record accurately, simply, and interestingly, the world's progress in scientifle knowledge and industrial achievement

#### The Unsinkable Ship

B ROADLY speaking, there are two ways to suffguard the fires of the passengers another the offreets of serbans cullibran at san. One is to crowd
the upper decks with Hicharts, providing a sufficient
under to accommodate everyone on bourd, the other
le to make the ship. Hs own Hichard by endodying
within it such construction that it is absolutely mediaable As representing the first method, the "Imperator"
is to-day luminered my with no less than eighty-four
Hichards and the new "Augultualle" of the Cumud Line
will come into port next summer with no less than alue
ty-two Hichards on bourd

The Semistric Austraces has currought mutualized that the rational way to breat the question has we to construct every large passenger ship, that he the event of sections have been expected upon the property of the propert

We note with satisfaction that at the twenty first meeting of the Society of Navai Architects and Marine Engineers, held to this city during the present month, distinguished unval architect, George W. Dickle, vice a distinguished manufacture, two got we predefined of the Society, presented a later paper in which he gave the general particulars of a ship build according to these principles. The drawings represent a modern presenger stemmer of about the size of the Protection against slutding is altorded by Thinke Protection against staking is almoded by a double, cellfular upper deck the feet six inches in death, the tower floor of which is located at about the normal water flue, and the upper floor, liconghout the middle portion of the ship, some five and a half feet above this The lower thou throughout the length of the boller stures is parallel with the keel of the slope. Levand the boller spaces it slopes down to a function with the stem forward and the stern off. Its form longitudinally being nerally sludbir to that of the protective deck of a warship. Forward of the boller spaces the accommo dation between the two floors of this waterlight deck is utilized to receive stores of all kinds. Aft of the bolier spaces, the accommodation is utilized for cold storage compariments. Over the todier and engine rooms this space forms what Mr. Dickle calls the 'satchase ment of the hotel part of the ship above." All ventilatbug ducks salt and fresh water males, and drahange olpes are arranged in this space, so that vertical piping only needs to be carried to the rooms above would obvinte the great structural difficulties involved in carrying horizontal piping ducts through the passen accommodations themselves; un improvement which

Mr. Dickle justly considers to be  $^{\frac{1}{2}}$ u very important feature of such u design "

The space between the floors of this upper deck would provide 9,730 tons of buoyancy, which, even if three of the large boller compartments below were open to the see, would still leave the upper thor of the deck materbilly above the water line—if the side of the ship, as rbilly above the water line. If the side of the ship, as lu the case of the 'Thank," were ripped open for a considerable partian of her length, below the lower floor of the upper deck, and the five large boiler compart ments were blied, 14,020 tons would be added to the placement. If the forward holds were flooded and it ary to flood the after holds in order to trip the ship, 3.000 tops of water would enter and the total the sup, 3, 50 1098 of water want erect and the com-amount whilm the slip below the cellular upper deck would be 21,000 tors, which would cause the slip to settle until the water was 0.36 feel above the upper or of the upper deck. To render the sldp safe agr sloking under these conditions, it would, of course, is sluking under these conditions, it wount, or consequencessary to so build her that there should be no it "lutes" or sidelights between the upper and shelter docks, through which water could enter. This difficulty decks, through which water could enter. This difficulty could be avereome by building specially strong sidelights with the class cost around a wire most us a protection against cracking

Mt. Dickle, who sured is an authority, pronounces such a slup mismbable, even moder the extreme conditions of feding flooded from stem to stem below this upper deel. Such microcontrolly, however, is extremely remote. The passengers who stepped ubsard this vased, would do so with the perfect assurance that the calmulty which overwhelmed the unfortunates on the "Hamle" would never overthes themselves.

It should be neutroned that Mr Dickle's plan protibles for the housing of the engineer and holfer-room forces within this double deck, through the center of which a continuous passageway would run, residering possible all needful intercommunication, and obtaining the necessity for staliway openium through the upper deck to the deck above.

ower to the deces are thus briefly outlined is practical. It does not hivide behasion within the ship of unused spaces, it solves the difficulty of pliping and wiring, and it provides an absolutely safe ship. If such constituenton were rendered obligatory by law on all the larger passenger ships. It would work no hardship upon either the indiffer or the owner, and it would remove absolutely and forecer the possibility of another "Pittanic" disaster.

#### Evolution and Ascension

IIE concept of evolution is very commonly assume thated with time of accession, the passage from A closer commitment of this beginning the subset in the health of the hea

There can be fittle doubt that govern1 rules cannot be lath down. The cause of colution will depend upon circumstances. But his of a risk general conditions of control control charge in the star is general conditions of control control charge in the star is provided to be probably as correspondingly constant trend in the cause of evolution. Under constant conditions the control control conditions in the control condition of the control conditions in the control condition of the control condition in the cause of evolution to proceed from shapler to complex forms. We say, as a rule, for there are majorationably exceptions to this, cases which may be described as degeneration, but which invertibles are consistent processed increased in consistent of the control conditions.

represent hereading adaptation to existing conditions. Now the goodnets and pineutotologist trac well acquainted with recruits sudden breaks in the geological recover, overshooted by some comparativity modeln or "outnot tophic" change in the condition of the earth's creat the admission of a continent in the count, our the consequence of hand from the sax, or more or less performed climate changes. Here the conditionary of conditions is broken, and forms of life which had become highly specialized, complex, a prilicularly well adapted to the conditions that had long nevalled, are now less that a geological "unconforming" is mainly compared that it is a production "inconforming" is usually examined to the computated by a sudden change in facel flow and frame, and that in this change the "highest" types are found to have suffered nost.

#### Antivivisection Hysteria

The close of the year which marks the twentyty-fith analysis are of the founding of the Pasteur Institute, It is tuiting to look back and
with grateful appreciation to survey the Institution to
such men as Pasteur, Tyndall, and Lister. We cannot
been attempt in exhaustive account of all the trimphs
liat have come to molletine and surgery through the
discovery of the busterlain ording to firefulous diseases,

and through the aseptic methods and antitoxin therapy based upon this discovery. We must be field to single out a few of the most significant fact Let figures tell their eloquent tale;

MORTALITY AMONG PERSONS APPLICATED WITH SEVERE

Ex-President Toft in an address before the Medical clubs of Philadelphin, on May 4th, 1013, stdl. "Of the volunteer regiments mobilised during the Spanish-American war, to per cent became infected with typiold fewer within eight weeks from the date of mobilization. To day, two mouths after mobilization, with modern health regulation and the use of vaccination against typhoid, not one case of typhoid fewer has appeared in the entire force, except that of one tennates, who was not vaccinated."

Recarding the ravages of yellow fewer during the reuse of the disease was understood, we quote from an article by Dr. Crosstein, as published in our issue of November 9th, 1912: "The family of a French chief engineer consisted of five; four died of yellow fever. Of the five members of the family of the superintendent of the railroad, three died of yellow fever. Of the trailroad, three died of yellow fever. Of the trailroad, three died of yellow fever. Of the trailroad, three died of yellow fever. Of thempty-five Nisters of Uncrity who came to Ancon Bospital, twenty died of yellow fever.

Contrast with this two distorting figures, taken from Contrast with this two distorting figures, taken from the first two distorting figures, the first figures fever by the Steen supin mosquite manual and yellow fever by the Steen supin mosquite manual and yellow fever by the steen accordingly: "Prom July 24, 2004, to June 1st, 1905, 77 cuese of yellow fever originated on the latitumes. In June 1905, 62 cueses: In July, 42; in August, 27; in September, 6; in Cother, 3; in November, 2; December (In Cothen), 3. In November, 3; December (In Cothen), 3. In November, 3; December (In Cothen), 3. In Pulm 1906 there was only one case of yellow fever on yellow fever has occurred on the Isthmus, ultimostin a continuous fullings of non-limitimes is taking taken.

We would like to extend this list of triumphs further, but space is lucking, and there is another matter on which we wish to touch. We will introduce it by a few further significant figures.

MORFALITY AMONG ANIMAIS APPLICAND.

Other discuses of animals which have been successfully attacked by methods built upon Pasteur's work are rinderpost, pleuro-pucumonia of cattle, Texas cuttle fover, swine cryslpcias, glanders, etc.

There are, unfortunately, some Hi-Informed, and, we add without inedution, ill-binned people, who seek to oppose the wonderful progress here recorded because it has been gained through experimentation upon unimals.

To the consideration of the more thoughtful among these we would commend the last quoted figures, which show that animals themselves have amply heavelful from such experhentiation. True, this argument will seem nancepastry to the unblassed reader who has per used the earlier paragraphs of our comments. But we are now speaking to the blassed reader.

As for the hysterical and Irresponsible antivisections, we will attempt no miscoloury work on him (or her), but shall feel that our function is fulfilled when we have warned the other members of the community of the telenomers of the members of the community of the telenomers of the members and attitude and the methods resorted to by such misculded persons. Those who wists to inform themselves in detail on this point are referred to a pampilier by 1r. W. W. Keen, "The Influence of Antivisection on Character," published by the American Medical Association—From this, to illustrate our point, we will merely quote an anonymous letter received by 1r. Keen:

"I have read with horror your article in the Ladies

Home Journal on viviacction.
"I hope your mother, it she is living, will die in the most terrible torture, and it she is dead, that she will never know rest for having given life to such a vile monster as you—is the nightly, prayer of a dozen women who indite this."

This, written to a man who is following in the footsteps of Pasteur, doing the noble work of the medical profession.

#### . .

The Court of the C

the state of Death on Referenda.—A contemporary has residenced that since the average length of a railroad necessary in this receiptry is 86 miles, and a passanger may lake 275,132 with journeys with only one chance of being killed, it would take him, at two trips per day, 8750 years to run the full genut of risk. That is to any, if the one fairly section of the receiptry is the sense fairly security for him to say it the one fairly section to appear of the relational traveling, at two trips per day, in the year 1879 B. C. It must be borne in mind, however, that he snight be killed on his very first trip.

Georgie Washington was as don time suggest in surveying weather to be a first of the modern engineers were the survey of the surveying weather than the present of the modern engineers were the survey of the surveying weather than the survey of the surveying weather than the survey of the surveying traveling to the survey of the surveying traveling to the survey of the surveying traveling the surveys. The attention which has recently been directed to this automate at the survey. The attention which has recently been directed to this automate of the survey.

scottable surveyor. The attention which has resembly been dispetted to this matter has called forth a wide-spread appreciation of the fact that he showed in this work of his youthful days many of those qualities which, in after this, served to make him one of the leading figures of his age.

The Bischned Suy Atlantic Routs.—Discussing the proposed short routs across the Atlantic pin Blacksod Bay, the Shipping World draws attending to the fact that passengers dislike very much the trouble and annayance of any tenenchipment, and American and Canadian traveless are not likely to take kindly to a railway journey across Ireland, a steamer passenge across the Channel, and another railway journey to serous the Channel, and another rulivary journey to their destination. Further, on the reverse journey, passangers will prefer to sunback either at Liverpool or Southamphon to bodge subjected to the innonvenience of going direct to Blankood Bay by train and a coasting teasure. Such a service could not be a success with-out handling a large amount of cargo, and as Blackood Bay is to far removed from the large industrial centers, this class of traffic is not likely to be attracted.

For the Comfect of the Beannes.—The Secretary of the Navy has approved the provision of a reception and reading room for the crew in the case of the U.S.S. "New York," now building at the Navy Yard, Brook-lyn. This consists of a commodious compartment in a location very accessible to visitors. In this room is to be located the crew illinsary, and also room in further to be fitted with reading tables, writing desks, paper and magestee ready, chairs and transom. Ad-jacent to this room are to be larvatory facilities for the nave of guests of the crew. This grouvison for a recop-tion and reading room for the use of the crew and their guests is a -new departure in warship design, and has been desagrated by the Secretary of the Navy for impressing the common of the crew and adding to the attractiveness of the skip for the calisted men and their visitings whis in part. For the Comfort of the Soumen .- The Secretary of e visitors when in part,

their visitors what in park.

Soft Butting Larent-dot. Rivers Plagg, the archi-ters, has done prod service in the criticism before the had done prod service in the criticism before the Lithershopi. Evaporation During the 1912 Haze.—The henceforth historic "haze of 1912" appears to have registered itself unmistakably in the evaporation records of the great plains and the intermountain districts of our western States. This subject has been discussed in a memoir by L. J. Briggs and J. O. Bels, of the U. S. reau of Plant Industry, on the basis of mee Bursau of Plant Industry, on the basis of measurements made at a number of waporating tanks during the past five years. As compared with the "normal" for its whole period of observation, the average evaporation measured at afteen sistings during the four months following the emption of Katmai was generally deficient, the average reduction amounting to about 10 per cent. This corresponds fairly well with the reduction in solar radiation observed by abbots and Fowle and by Kimbail during the same months.

The Composition of Cows' Milk may be materially modified by the effects of certain drugs which are in common use in medical treatment, such as sodium sul-phate, magnesium sulphate, rhubarb, aloes, and arsenie. phase, magnessum sulphase, rhubarb, aloes, and aremie, according to recent descreteries of O. Lamonin, justilished in La Cifestee Veterisoric. In the writer's experiments all possible precautions were taken to eliminate the indicases of other factors affecting the composition of the milk, such as breed, age, time of milking, feeding, ale, patchedgeal and physiological conditions, etc. Two exceptions and mysiological conditions, one. Two exception of milk space taken from each cow, one before and the orther street the administration of the inadhning. It was from the dark the decreas produce considerable is intensitient to the characteristic contractions of the suffix, which silved its chief nutritive consistents. of the smill, which affect he chief surfaire constituents. The alternibus, andsy consists in the loss of all nutritive property, owing to the playing decrease in the total solids, or many makes the smill; simulable for food, e.g. from an anosis of confin reindering it indigentible. Such milt can such angulation, and should not be suid except for special purposes, and mader the names "medicinal milk."

#### Aeronautics

Another Parachute for Aeroplanes.—The question of parachutes for aeroplanes so as to allow of a safe ent continues to occupy the attention of inventors. Numerous experiments are being carried on in F and it is now stated that a Berlin police lieutenant has invented a new parachute which differs from what has been heretofore presented, for the parachute surface is operated in connection with the wings of the acroplane. On his scheme, a large surface of cloth is rolled up and attached to the wings, this being released by a lever so as to spread out and allow the flyer to descend alowly to the ground.

The Carnegie Museum to Have Rodgers' Transental Aeroplane.—All that is left of the historic t biplane with which Calbraith P. Rodgers flew from the Atlantic to the Pacific two years ago, is to be presented to the Carnogic Museum at Pittaburgh by the late aviator's mother. The machine was badly by the late aviator's mother. The machine was bedly damaged when Rodgers fell to his death in the Paosite Ocean a short time after completing his wonderful flight. Subsequently it was used by Andrew Drew until that aviator also was killed with it. The machine has been restored to its original condition and will no doubt be prized by the museum to which it has been presented. This Wright biplans is the only machine that has flown across the continent of North America. Both Redgert and Powler's Wright machines have motors of but 30 horse-power, yet they flew across the continent in opposite directions at a time when the aeroplane had not been equipped with the 100 horse-power motor of to-day, which makes it much more stable, nor had it developed anywhere near the second of which it has since shown itself to be canable. has been restored to its original condition and will more stable, nor had it developed anywhere near the speed of which it has since shown itself to be capable. Robert W. Fowler, the second transcontinental fire, is at present engaged in making bi-wockly tryps between Oakland and Oroville, Cal., for the purpose of locating brokes wires for an electric power company. An electricism ascompanies Fowler and makes repairs.

Testing the Gas-tightness of a Balloon. The followresults the cust-inguistics of a station. The follow-ing method was used for testing the "gas-ingitiness" of the balloon fabric used in the balloon "Goodyear," which won the 1913 Gordon Bennett Cup. A defantic area of the fabric was placed between the halves of a gas-tight drum and the drum-sections firmly oldamped to-gether, thus forming two chambers with a wall of fabric between. The bottom chamber was connected with a source of highly purified hydrogen, the upper chamber with a compressed air numeric line, and activation source or nigary purned nydrogen, the upper chamber with a compressed air pumping line, and exhausting itself into a combustion train. The gas-tight drum was then immersed in a tank of water, maintained at a definite, unchanging temperature, and hydrogen was admitted to the lower chamber of the drum at a consumired to the lower channer of the druin at a con-stant pressure equal to two inches of water. As the gas diffused upward through the fabric and into the top section of the druin, it was swept out by the air cur-rent and carried through a glass tubo filled with platinrent and carried narrough a gines tube most with piani-ised asbestos hested to redness. This material caused the oxygen of the excess air present to combine with the diffused bydrogen to form water. The water thus formed was absorbed in a sulphuric seed hulb and weighed. By determining the weight of water in a unit of time, knowing the area of fabric under examination, well as the gas pressure and temperature within the drum, it was possible to calculate exactly the number of cuble feet of hydrogen diffused per square yard in 24 hours at the temperature and pressure of the test.

A Novel Experiment in an Aeroplane.—The vertical descent of an aeroplane is a performance which caused some surprise to those who witnessed it at the Buc grounds near Paris. Vicomte d'Autroche is an experigrounds near Faris. Vicomic of Authorite is an oppor-enced military pilot and was engaged in the recent army maneuvers with the aeroplane corps. In the course of the maneuvers he took note of the fact that the seroplane was called upon to spot a certain point on the ground, then pass above this place and let drop a bomb, but it became evident to him that it is very difficult to place the bomb while in rapid flight, and the object could be much better attained should the aero plane remain motionless overhead, or else drop or settle down in direct vertical movement so as to approuch nearer ground. He exercised in order to produce settling down movement, and was soon able to do this; thereupon wishing to prove its possibility he approached Maurice Farman who was at first increduapproached Maurice Farman wine was at mix incremi-lous, for such a vertical descent in flat position had never been seen. But he was able to prove this at the Bue grounds not long ago. When at 3,000 feet height and in a wind of 60 feet a second, he appeared to stop and in a wind of 60 feet a second, he appeared to stop completely in the sir and the propeller turned very slowly. Then the seroplane descended to the ground in the vertical line, but all the while keeping the tenul flat position without everturning. This he repeated several times, and even with a passenger on board. The pilot begins at say height placing himself against the wind, stops his motor and allows the aeroplane to decessed. When 200 feet from the ground he starts the motor and alights as usual. He used a Farman biplane.

#### The Great World Wireless Circuit

#### By J. F. Springer

THE Merconi Company is now engaged in the construction of seven or eight great long distance wireless stations. These will form links in a world telegraphic circuit. One or two in-tervals where land is to be trawed will be covered by means ordinary methods. The re maining intervals where enormous bodies of water he between stations will have long distance wireiess transmission. The sta tions now in contemplation or under actual construction are locat ed in New Jersey, Wales, Egypt, India, Japan, Hawalian Islands and California.

The system of transmission is

that known as the directional, That is to say, the aerials are arranged to extend along the line

of transmission. For example, at Beimar, N J., two straight-line aerials of silicon bronze, each a mile long, will be arranged in parallel straight lines discorded toward the transmission portion of the Welsh station with which communication is to be established. More precisely, these aerials will lie on a great circle of the precisely, these aerials will not a great circle or the earth passing through the two widely separated points. Wireless impulses emanating from Wales will find along this circle the shortest path to their destination. Further, it would seem as if the similarly arranged aerials in Wales would send their strongest impulse along the line of their direction, and that the aerials

at Belmar would accordingly be finely situated to catch the almost exhausted ' as they complete their great 'waves'

Belmar will be the receiving portion of the New Jersey station. The transmission aerials will be located thirty miles away at New Brunswick. However, the hand of the transmitting operator will be at Beimar. Ordinary telegraphic methods Helmar. Ordinary telegraphic methods will be employed to carry the message to Now Brunswick. Here, automatic wire-less keys will transform the Morse mes-sage into a wireless one which will strike out across the Atlantic to the Welsh coust. The dozen of nerials at New Brunswick will be directed also along the shortest path to their objective point. The New Brunswick transmission apparatus is located so far away from the receiving aerials at Belmar in order to reduce by distance their interference with the weak impulses coming in from the Atlantic outo those aerials Further, the impulses going out from New Brunswick will presumably be strongest along the line of their serials and weakest along a line at right angles to it. Now Belmar actually lies on a perpendicular to the great circle passing through New Brunswick and the Welsh through New Influmence and the weish station. We may see then that these loca-tions were not selected at random, but with a perfectly well-defined object in view. By taking a map of New Jersey and laying off a line from New Brunswick in such a way as to make with the meridian

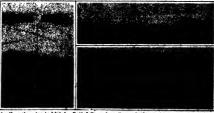

an angle of 50 degrees east of north, and another ru ning from New Brunswick to Belmar, the two lines will be found to be perpendicular to each other; the former lines extending in the direction of the Welsh station.

While the acriais to be held in position are very slight themselves, still the fact that they have to be maintained under tension at a very considerable height imposes serious construction problems. The elevation at Beimar will be about 400 feet above the ground. The six steel masts or towers which will support the little wires will consist of tubular sections, each ten feet high

(Concluded on page 408.)

## Fighting With Dyna and Electricity

#### By Dr. Alfred Grad

A GLANCE at the history of strategy reveals a tendency noticeable in nearly all branches of human activity, vis. : a gra al superseding of the int y collective labor organic ntrolled by a few sun valor, once the most important factor in warfare, has been reduced to a secondary role. The This entenana with the introducti as of r and continued apduring the nineteenth co with the rapid strides made by

with the rapid strides made by engineering. Islice industry, warfare is be-coming more and more mechani-cal. Soldiers are now hardly more than tools in the bands of their capitains. The issue of a sat entirely on numbers and post-

tions. Personal bravery is not of prime importance. In place of it we have something like collective valor, a morale which may to some extent determine victory or defeat

One of the latest stages in this development is the attempt to eliminate the personal element, the soldier, entirely and to substitute for him a machine or automaton. Something of the sort has actually been lit-tempted by a Norwegian engineer, Mr. N. W. Assen, whose "mine greaades" work practically without the help of soldlers, spreading death and destruction every-where. His contrivance is illustrated in

the accompanying diagrams, Fig. 1 show-ing the grenade in position in the field, ing the grando in position in the med, and Fig. 2 at the moment of explosion, representing the spreading of the projectiles. Fig. 3 shows a double shell barricade 1,200 yards long and 100 yards wide, made up of 50 mine grenades joined up in two sets, and which on exploding, sweep an area of 108,000 square yards. Each grenade, inclusive of its accessor-

ies, weighs about 9 pounds, and contain 400 projectiles and about 12 ou an extremely powerful exploan extremely powerful exposure. Im-greande consists of an iron cylinder with a conical point which constants in its in-terior the projective and explosive charge as well as the mechanism consing the greande to rise from the ground and eventually to explode. This mechanism can be set working only by the action an electric current supplied to the great through a flexible cable.

At the bottom of the cylind a small powder charge which by the electric current and win the shell hody vertically thiron a chain, the opp to the cylinder

## Skin Defects in Invisible Light

### A Method That May Have a Wide Application in Medicine

By G. Michaud and F. Tristan, Costa Rica State College

an ter

eer made, hi two different regions of the uniter-ricide spectrum, two large photographs of the head of a man his pears old. For comparison purposes a third photograph was used in visible light and an other in the invisible infra red light of the appopie was of the spectrum. Figs. 1 to 4 show the results of the expectant. The accompaning diagram (Fig. 5) gives, in Amgelvius units, the sanct wave length of light used for each photograph and also the nature of the filter used to select such wave lengths out of direct small select such wave lengths out of the light of the state of the same light. #### Radium in Agriculture

A (CORDING to recent experiments in Europe it appears that radium is instrumental in preventing discuses of plants, whence is likely to arise

a new application of this interesting ele ment in agriculture. For several years workers in agronomic science have been experimenting upon the effect of radium upon vegetation by mixing radioactive substances with the usual fertilizers. The numerous results obtained in this work show that most plauts either grain or fl wer are remarkably stimulated and give s better yield both in size and quality this being often seen in the flue and he color f the green plants or leaves I nder the same plants are in better conditi n to resist attacks from various sources of discase such as cause so much damage to crops especially diseases known as crypt) gamic which arise from spores or mold. It seems that radium is to not as a pre-ventive for such discases as wheat rust rotting of potatoes grapevine mildew and many others which cause such detriment to agriculture. Such a result is mly to be expected from what we know as to vital phenomena in general and among others as concerns the human body for all influences that tend to reduce the ltality of the system are likely to leave it a prev to harmful outside influences and infections Such results in the appli-cation f radium in agriculture are likely to be far reaching

## The Autograph of an Iceberg

#### The Thermometer Not a Danger Signal That Warns the Mariner of Nearby Ice

By L E Browne

THE Bureau of Standards has completed initial extrements in solving the hazardous techerg clement accountered in navigating the North Atlantit. Geen during certain seasons of the year Professors C W Mediner H C Dickinson and 1 J Crowe made observations of sea water temperature near techergs and in the open sea with apparatus installed on the United States crubsers. Chester and Birmingham with a view to determining the possibility of detecting the proximity of techergs from temperature records

The apparatus consisted of an electrical resistance thermometer with fish' I had a mid another with 15th foot leads out another with 15th foot leads of the unlimber compensated type with four feathlies silk-evered c lie of itskel wire of 100 ohms resistance. There was a surface electrical resistance made or a flat coil of silk-evered nickel wire inclosed between sheets of copper and insuitated by which sheets of mic A lies others were several mercurial thermometers of the Ns prett and Zambra type loaned by the Bureau of Fluideries if redep set use

A recorder was meanted in the typedo room. This was so carefully laisunced that the records were not influenced by the rolling and itfelting of the ship. Con tinuous records were obtained fr m June 4th to July 10th. The surface thermometer was unused with its dated against the luner surface of the ships % inch plates about six feet below the water line and the whole covered with a thick layer of cotion to eliminate the effect of the warmth of the torpedo room.

For the purpose of defermining whether echoes could

For the purpose of determining whether echoes could be detected from ischerge under water the ship a bell was lowered into the water and struck. Observers statuoed at the submarine signaling reviewes heard several faint echoes. The ship was at a distance of from ne to two miles during the tests. If there ind been time to improve the tnatruments a solution might have been found, founded on the each theory. The camulassion has recommended that it be still further investi

It was found that the effect of cannon fire on leeberg was small. The use of searchlights in locating lergs was determined as practically fattle. Lookouts stationed on deck invariably saw the bergs before men with glasses or in the tops. Water meisted from large chunks of lex taken abourd the Chaeter from a branch aboved that berg lee has great quantities of inclosed air which probably accounts for the bergs withink appearance. The density of this water was the same as that of distilled water. Air temperature observations aboved that the lockery, has very little influence on

the temperature of the sourrounding air
Temperature records showed that the variation in
the warmth of water many miles from a berg is often
as great as that in the vicinity of an icohery. The
commission reports that it will probably be impossible
to establish set rules for detecting icebergs by means
of temperature observations.

The Bureau of Standards party formed the conclusion that the characteristic isothers' effect upon the surrounding water as described by Prof. Barnes was not true. Our records abow an opposite effect to that noted by Prof. Barnes the deposite effect to that noted by Prof. Barnes theory is that there is uniform ity in the rise of temperature of water as the berg is approached and then a sudden drop. The party moted as gradual drop in temperature as the berg was approached from a distance of several railes. The official report of the Bureau party which has been east to navigators throughout the world is in part given in the conclusions below:

If the levelers is constantly drifting into new waters its conting effect on the ocean would be extremely applied from the consideration of the fact that it would sequence the melting of about a million tons of too to cool seasuare mile of open to a depth of 25 feet by 1 deg. Clent. The possibility of extender conting action would require that the berg and surrounding water drift together her considerable distance and that the heation be slow

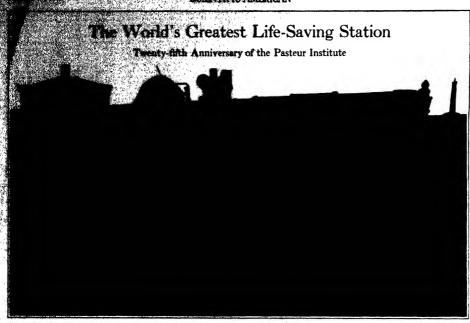

This is probably true under some conditions, but by so means always. Conditions such as these yearler it desirted it any appreciable effect could be distinguished with any degree of certainty at a greater distances than a mile. To account for his beer, Prof. Barner assumes that in regions of the ocean at some distance from the beer pice surface layer, heated by solar refdation, is mixed with the celd water below the 'social vertical circuition, white near the beerg there is a current set up toward the being due to the countines offects of the melting and cooling action. Barnes assumes that this current interferes with the desculation to that the warm water research on top, it is difficult to understand how a sufficiently strong current could be set up by the setting of the beetg to prove they wife the normal circuits. That there is no vary strong current toward, the beetg is proved by the fact that on breaking of the best proved by the fact that on breaking of the large and small chanks of los drift away from the beetg.

"The records of sea water bestperature show that his variations in parts of the open far sensored from helbergs are often as great and spidien as in the seighinghood of seabarm.

used light, he soived the problem of the different forms of tartaric acid. By this work on britaric acid, which is a grape acid, he was led to his discoveries in the kingdom of the fernmants. He was at work for more than a quarter of a centrary on the subject of fermentsion; and he introduced great improvements into the methods of brewing, distilling, vinegar making, and wise making. It was well said by Huxley of this part of Pasterie's work, that he had saved France more than enough to pay the indemnity of the France-German war.

man war. In 1965, without leaving off his work on ferments, Pastest took up the study of the silkworm disease, which was wrecking the silk trade of France. After five years of labortous work on this subject, he discovered and proved the infections character of the disease, and was able to restore prosperity to the silk trade.

Next he took up the study of the infective diseases of animals higher than dilworms: anthrax in sheep and cattle, foul cholera, and swine expidelas. His protective treatment against anthrax has by this time antiquarded millions of sheep and cattle against that disease. Reports from France and from Hungary show a reduction of the death rate on many farms from 10 per cent to 1 per cent among sheep, and from 5 per cent to less than 1 per cent among cartle

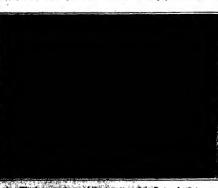

During these years (1870-1880), and for some years

During these years (1870-1889), and for some years before 1870, Fasteur, Lister, Tydall, and other men of acleace in diverse countries, were founding and proving the antiseptic and asspite method of surgery. By this discovery, they canbled all surgeons to save lives and timbs which, before the days of l'asteur and Lister, would have been lost. It is impossible to set a limit to the number of people who owe thoir lives to the work done by Tasteur and Lister.

The preventive treatment against railes was the last of Pasteur's great discoveries. But, iong before he died, bis work was extended all over the world. Between 1880 and 1890 men of science working on Pasteur's lines had discovered the germs of tuberele choiers, in last diphtheria, riphold fever, lockjaw, and Malta fever. In 1893 cmme the discovery of diphtheria autitoxin, and of the protective trement against choiers: in 1894-7, the protective treatments against the discovery of the germs of plague, and of the issues fly discover; in 1895-7, the protective treatments against typhold fever and phague; in 1885-1000, the final proofs typhold fever and phague; in 1885-1000, the final proofs

Sphola sever and peages, in some land peages that malaria and yellow fever are conveyed by special kinds of mosquitors; in 1903-6, Bruse's work on sie-ping sickness and Malax fever; in 1907-10, Fietzner's work on agid-denie meningtists and on spidemic infantilic paralysis, and Earlich's work on the treatment of a widespread contagious disease. These and other life-awing discoveries have been given to the world, as it were, by the hands of Pasteur. Nor is it only men, women, and children who owe their lives and their health to him. The diseases of animals, no less than the diseases of the children of the contraction of the second of the contraction of

He died in 1895. To-day, whether we look at surgery, or at medicine, or at public health and sanitation, or at veterinary surgery—over the whole face of

work lives, and his methods are extended, for the sav-

work lives, and his methods are extended, for ting of human and animal life and health.

As aiready stated, the cure for rables was Plast discovery. When we remember the last discovery when we remember the latture of the discose, we may well imagine wit the horrible

enthusiasm the announcement of the new cure was received. The French Acad-emy of Sciences made an international appeal, in response to which two and a half million francs were obtained by public subscription, and in November, 1888, President Carnot dedicated the institute that bears l'auteur's name.

It is interesting to recall some of the incidents in Pasteur's researches on rables. He was experimenting with rab-bits, and observed that the spinal cord of subjects dead of rables became those-uous after drying for two weeks. He inoculated dogs first with this two-week old vaccine, then with virus 12, 10, etc., days old, and finally with perfectly fresh s, when it developed that dogs sub mitted to this treatment had become immune to infection. After making his communication to the Academy of Medicine Pasteur was stormed with requests to extend his treatment to man. conservative attitude toward this matter is shown by his reply to a letter from the Emperor of Brazil. Pasteur says: "Even after numberless experiments on the action of anti-rables serum with

dogs, it seems to me that my hand will tremble when the time comes to experiment on man." But circumstances forced him to make the trial sooner than he had anticipated. A young Alsacian boy was brought to him, with fourteen bites from a mad dog Only after having obtained the consent of the dean of the Faculty of Medicine and of Prof. Grancher did

On July the 6th, Pasteur take the mon entous step.

reaseur tase to momentous step. On any two visions, 1885, the first vaccination against rables was performed, and the hoy's life was saved. Shortly after the second case was treated, a young shepherd of the name of Jupille, who from that date remained in faithful ser-

vice to Pasteur. Jupille has become a historical figure as is only fitting, for he received his wounds in protecting a group of children from a mad dog, whom he strangled. This episode furnished the subject for an appropriate statue now in the grounds of the Pasteur Institute. The young shepherd is shown struggling

ally produce any very sharp impression of color upon the retina, sithough actually the same dispersion of light corurs as in a daytime bow. However, the impression prevailing even among on prevailing even among

tinctly colored is not borne out by sa examination of the files of such journals as the Meteorelogieche Eeltechrift, Symons's Meteorologieche Eeltechrift, Symons's Meteorologieche Megesine, etc., in which many descriptions of these not-ternal phenomena have been published. In fact, this pappeas rather more often than not that a lunar rainhow brilliant and striking enough to be thought worth reporting to the scientific journals is described as show-

Proporting to the Scientific Journal to Security of the Color ing the colors distinctly. It seems immediately to discuss Mr. Nash's observation further, inasmuch as we commented at length on a similar observation a comple of years age. See Scientific American, May 6th, 1911, p. 447.—Ruirea,]

#### The Double Report of Projectiles

To the Editor of the Scientific American:

I was somewhat surprised at a note in your corr e column in the issue for the 18th inst., which states that there is some doubt as to the cracking sound, or sound of a double report, noticeable when a high-velocity projectile passes. This sound, which may seem louder than the report of the piece if the latter is fir from a distance, is only noted in projectiles of a greater velocity than 1,100 foot-seconds, which is about that recovery usual state from the about that of sound waves, and is caused by the builtr passing through the atmosphere. As its velocity is equal to or greater than that of sound, its arrival at a point opposite the heart precedes that of the sound waves it est up at an earlier stage of its flight, and the sharp crack the builet makes is caused at that part of its fight opposite to or nearest the hearer. As it recedes night opposite to or nearest the neares. As it receives from the heaver, the sound waves apparently follow it away from the heaver, and do not come arrongly back to him, and they are diversed set by the relatively more intense sound made by the projectile at the meant to him, and they are diversed out by the relatively more intense sound since by the projectite at the instant it passed him. If, however, the parson noting this physicismon in at shome distinge from the line of flight of the projectile, he hears the acute made by the projectile over a considerable part of its course blending with and following libe (harp report it makes as it passes him, and if his needstile, is surfaciently determi, the report of the projectile so blends with this visitating or rounting sured as to be nearly lead in fig. 12. In the coing of a small belief, the acused much passentials the experience of the projection is observed much in fi. In the coing of a small height, the second much passentials the sangle of a large projectile with goods made in a train is a trained or covered pricipe life, it follows that the same of a large projection will it has presented him; therefore, and is colded the flower own involve status him. A comply infinite is not detent higher flow is present the content of the property of the content of the project of the property of the project of the project

is due to that low velocity, often distorted shape, and erestic dight. In coordigaton I note your correspond-ent's use of the term "steel-jacketed builet." I have been daulified with modeln small arms and ammunition over twelve years, and have used ammunition dating ok as 1896, and have never seen a steel-jacketed as fir hark as 1800, and pure news sould damage and soon spell the lands of the barrel, owing to the hardness of the steel, and thus ruin the rifling. The material used is a cupre-oticle alloy, considering the necessary tough-ness with a texture sufficiently soft to preserve the riding.

G. W. Engranz, First Licutement Fifth Infantry. Platisburg Barracks, N. Y.

#### Tidings from the Poles

THE attainment of the terrestrial poles has, contrary to general expectation, increased rather than dim-inshed popular interest in the subsequent activities of circumpolar explorers. One token of the growing popuof the subject is the large amount d to it in the daily press. Latterly it has become an established custom for the leader of a polar expedition to contract with a great newspaper or group of spapers for a series of detailed reports of his evenuents, to be rendered by cable as often as circumstances permit. Thus the New York Times is the accredited mouthpiece of the Canadian Arctic Expedition, and the New York Tribune of the Crocker Land Expedition. So well is the task of reporting these polar undertakings now carried out, in comparison with the methods of a few years ago, that one is encouraged to hope for still further improvement in the near future.

hope for still further improvement in the near future. For example, it does not seem too much to expect of the great press associations that they should have all news of polar explorations and discoveries edited by an expert geographer before sanding it broadcast over the land. A complemons illustration of what is likely to happen in the absence of this precisition was afforded has October when the discovery of Nicholas II Land was heralded throughout the country as the discovery of an Arctic "continent," or "land as large as Green-The first dispatch from St. Michael, which stated the latitude and longitude in which this discoverg was made, should have enabled the veriest tyro in Arctic geography to recognize as impossible the existarge land mass in the reported location; yet eace or a sigh man mass in the reported location; yet not only did the newspapers all over the United States publish whose columns dilating upon the attainment, by the Russian expedition, of the identical "continent" which the expeditions under Stefanson and MincMillian are now seeking, but they cited in support of these vagaries some presumably much-distorted interviews with polar authorities of the highest rank—who can hardly yet have ceased to blush over the fatuous reattributed to them on that occasion marks attributed to them on that occasion Another curiosity in polar news was the Associated Press dispatch of August 27th, 4918, announcing that Dr. Dou-glas Mawson and five companions had been rescued in a starving condition from Macquarie Island. It would a startying community from an equipment is such a from the extremely interesting to ascertain whether a single newspaper which published this "story" commented editorially upon its manifest inaccuracy, or has since taken the trouble to publish a correction. Mawson was, of course, not at Macquarte Island, where he establi a radiotelegraphic station on his way to the Antarctic, but in Adelie Land, on the Antarctic continent, and could not by any chance have been reached by a relief expedition at that season of the year Again, may we not reasonably ask for a little more

care in the spelling of personal names? Even if mis-takes in spelling are inevitably made in telegraphingand we believe they might easily be reduced to a minimum if verbal accuracy were not so lightly regarded by the newspapers—surely a well-informed editor could by the newspapers—surely a well-informed editor restore most of the bungled names to their correct graphy before they appeared in print.

graphy before they appeared in print.

These is a certain Australasian member of the Canadian Azetic Expedition whose name has, to our knowledge, appeared in eight different forms in press dipatches of the past few months, and some of the spetings are so erroneous as to diagnize effectually this
individual's identity. One need not be a purist to individual's identity. One need not so a purist to demand something better; for there are doubtless some newspaper readers who would like to look up the his-tory and scientific standing of Staffanson's ethnologist —an indispensable prailmanry to which process is to ascertain the gentleman's name!

Balance of Peru TyriHE fragment billeum imported into the United States as believe imported into the United States as believe of Fern a produced by a tree known betanically self signospine persigne known as broad on the Pacific Gear of theoret a merica, known as the flatess Coast, a trace; of land which formerly belonged to Ontennate, The coast was no named because originally balant was the only article that was callected and adapted away from the broad The Fern d and shipped away from that region. The tree

is found growing wild only along the west coast and in some localities it often occurs in dense forests. The balaam was long erroneously supposed to be a product of South America. In the period of Spanish rule, and by the commercial regulations then existing relative to the fruits of the coast, it was usually sent by the rchants here to Callao, Peru, and from there shipped to Spain, which accounts for the name of balsam of Peru, because it was considered indigenous to that region. The real place of its origin was known only to

At the present time balsam is shipped direct from points along the Balsam Coast which extends from Acajutla to La Libertad. The citief wealth of this coast is balsam and the trees yielding it are very numerous and apparently limited to one species, for in no other part of the coast, seemingly identical in soil and climate, are natural grown trees met with. Latterly the tree was introdu ly the tree was introduced into tropical Africa to the East Indies. The balsum tree is said to thrive very well in Kamerun in West Africa A num-ber of small experimental plantations have been started, and it is believed that a very profitable balsam industry will soon be developed there. It was planted as early as 1861 in Ceylon, and with complete success A considerable quantity is yearly collected from trees which were planted near Calcutta, India, and Central America balsam trade is now receiving some competifrom these points.

The manner employed by the Indians of the Balsam Coast in collecting the resin is very crude. Incisions of from nine to ten inches long and about two inches wide are made in the bark of the trunk. The areas made in the bark of the trunk. from which the bark has been removed are wrauped with rags, and the tree being previously heated by a brisk fire around it, or by means of torches, exudes a gummy substance which is absorbed by the rags that are allowed to remain on the naked wood for a few days, when they are removed and placed in a pot of boiling water, which separates the gum from the rags. They are taken out before the water cools, and the realn, which has a greater density than water sinks to the bottom and is collected after the water is poured off. The rags are removed from the water while they are still hot and submitted at once to heavy pressure for the purpose of obtaining the balsam still attached

The baisam is imported in large earthen-ware pote of a pear-shaped form partly covered with basket work, or in tin canisters. The balsam is a thick looking liquid, with a fragrant aromatic odor and taste. It is used in medicine as a stimulant, and also for making spills for lighting candles in churches and for torches

amount and value of imports of balsam of Peru from Central America during the past seven years have been as follows:

Year.		Amount Founds	Value
1905		20,835	 \$17,114
1906		15,747	 10,848
1907		15,303	 11.817
1908		25,021	26.171
1909		25,843	 24,217
1910		50,363	49,132
1911		37,910	 47.840

The tree, which yields the commercial balsam, is about 45 feet in height, and from 12 to 18 inches in diameter at the base. The trunk often grows to the height of from 6 to 9 feet before it puts forth any branches The wood is of a close grain, handsomely veined, nearly of a mahogany color, but redder. It has veined, nearly of a managany color, but redder. It has a very agreeable dotr, which it retains for a long time and takes an excellent pollsh — Balsam wood is highly esteemed for cabinet work, but is rarely to be obtained, aince the trees are seidom felled for the wood they

#### The Canadian Arctic Expedition

THE Canadian Arctic Expedition has not with a ser-I has of misadentures, culminating in the unpremedi-tated separation of its leader, Vilhjálmur Steffusson, with six of his men, from the rest of the "morthern" party on board the "Karluk." It appears that this vessel spent most of August and September drifting helplessly in the ice off the arctic coast of Alaska. On Septe ber 20th, believing the ship fast for the winter, Stefansson and a small party went ashore on a shooting expedition. While they were thus engaged the "Karluk" went adrift in a violent northeast gale, and h since been heard from. Rumors are now rife of diss sions aboard the "Karluk" prior to this occurrence, but the hypothesis that the leader was intentionally abandoned can hardly be taken seriously. Stefansson re-ports that he will proceed eastward to iterschel Island, after leaving an ethnologist and two Eskimos at Harrison Bay to study the natives of that region. During Mackenzie deita, and siedge journeys northward over the sea ice, possibly as far as Banks Land or Prince Patrick Island. the winter he intends to make extensive surveys in the

Kammerlingh Onnes—Nobel Prize Winner
FOR forty years past Kammerlingh Onnes has be
spending his working life in a laboratory specia ratory specially called into being for the production of the lowest tem carried into being for the production or the lowest tem-peratures attainable. For hearly twelve years there has been one goal before him: to liquefy the last ga-which still resisted the greatest cold as yet experi-mentally produced. This gas was, as our readers know,

saion of workers, from Callietet and Pictet (who were the first to liquefy alleged "permanent" games) down to Dewar, who liquefied hydrogen, had carried off brilliant victories in this field of science, but one gaseous element of our pianet still refused to yield to all endeavors to evidence it in the liquid form:

In his cryogenic laboratory at Leyden Kamm Onnes first attacked the problem from the point of view of theory. When his mathematical investigations were complete, he started out on the decisive experimental

By an ingenious arrangement of successive tempera-ture drops or "assender," in effect produced a tempera-ture of -90 deg. Cent. by means of liquid methyl chloride, then -106 deg. to -105 deg. Cent. by means of ethylene. Liquid oxygen then gave hin temperatures extending from -188 to -217 deg. Cent. Hydrogen furnished the next step down to -228 to -250 deg. Cent Not until this point was reached did the By an ingenious arrangement of successive tempera

perations with helium begin. It sed to over 75 atmospheres and coo in a bath of liquid hydrogen, and at -259 de-grees the helium condensed to a bluish liquid, whose temperature, on boiling, fell to -271 deg. This is only two degrees above the abs iute zero which, according to theory, is the lowest temperature attainable hy any means what

Calculations made by astronomers and physi-cists show that the temperature of interplane-tary space is about — 209 deg. Cent., a degree of cold which has thus been exceeded in the laboratory.

At these extremely low temperatures matter no longer behaves as at ordinary temperatures, The electrical conductivity of metals approaches

To produce these extremes of temperature it mry to work with minute quantiti gas and to use excessively fragile and delicate

The estimation of the temperature obtained by the liquefaction and evaporation of helium is somewhat arbitrary, for a reliable gas thermometer cannot of course be found for these conditions. The only means that remains for gaging the temperature is the use of approxi-

gaging the temperature is the use of approxi-mate formula and extrapolation. There would therefore seem to be no gas left on the liquefaction of which physicists should have spent their efforts. However, in the upper atmosphere of the sun a new element has b atmosthere of the sun a new element has been discovered, corunium, whose spectral line appears in the light of the solar corona. It is probable that this element exists, though it has never been isolated in the atmosphere of the earth. Some day this may be accomplished, and the problem of liquefaction will arise anew.

"Little Holland" has every renon to be satisfied with the distribution of the Nobel prizes.

In 1901, the first year they were awarded, a Dutchman, Prof. van't Hoff, received the ch The next year Prof. Lorentz and Prof. Zeemann shared the science prize. The following year again the science prize was awarded a Dutchman, Prof. Vander Wanls. In 1904 Prof. Asser received the peace prize, ils. In 1904 Prof. Asser received the peace prize, this year we once more congratuiste Holland on the trophy won for it by Kammerlingh Onnes

#### To Our Subscribers

WE are at the close of another year—the sixty ninth of the Scientific American's life. Since the subscription of many a subscriber expires, it will not be amiss to call attention to the fact that the sending of the paper will be discontinued if the subscription be not renewed. In order to avoid any in-terruption in the receipt of the paper, subscriptions should be renewed before the publication of the first lesue of the new year.

To those who are not familiar with the Scientific AMERICAN SUPPLEMENT A WORD May not be out of place. The Scientific American Supplement contains articles too long for insertion in the Scientific American, as too long for insertion in the Schertiff America, as well as translations from foreign periodicals, the information contained in which would otherwise be in-accessible. By faking the Schertiffo American and Rupplement the subscriber receives the benefit of a reduction in the subscription price.

#### How Hollow Steel Piles, Compressed Air and Concrete are Employed to Make a Poundation

RAPIDITY of building construction RAFIDITY of building construction is of primary importance in every city of nettopolities arise. When real estate is sold at the rate of several hundred dollars as quare foot it is self-evident that time is indeed money. The delay of a few days in completing a structure may deprive the owner of the chance of serting thousands in rental money. Because of the excessive depth of an open catson, the completion of a foundation may be delayed for months. Hence the building may not be completed until the renting period has a series of the cover may take an entire year before d and the owner must wait an entire year before passed and nee owner must want an entire year occure he can expect any financial return on his investment. Because rapidity is so essential in city building con-struction the method of first sinking an open pit to rock in providing a foundation has been displaced to a large extent by a system in which heavy bollow steel piles are employed in clusters to support a building. The hollow piles are driven through quicksand to rock, cleaned out and ultimately filled with concrete.

In this method of constructing foundations, which In this mernon or constructing roundations, wages is illustrated on the opposite page, below steel plies are driven in the well known manner down to solid rock. The steel plie sections vary in teugth from 20 feet to 22 feet, and in diameter from 12 inches to 24

Kammerlingh Onnes, winner of the Nobel prize in physics for 1913.

If the ground is to be penetrated to a depth greater than 22 feet, the sections of piling are connected by means of a sieve in such manner that a waterlight joint is formed. Under a pressure of 150 pounds to the square inch a jet of compressed air is then employed to blow out the earth and water contained within the shell. A spouting geyser of mud rising sometimes to a height of 150 feet, and occasional large pieces of rock s negation 100 teet, and occasional large pieces or roce-blown up from a depth of 40 feet below the ground, bear testimony to the terrific force of the air blast. When the shell has been completely cleaned out by means of the blast of compressed air, the exposed rock

can be examined by lowering an electric light. Steel sounding rods are employed to test the hardness of the rock and to detect the difference between soft and hard bed rock. After the piles in each pier have been cleaned out, they must be cut off at absolutely the same height netimes a very difficult task when there is little The oxy-acetylene torch is used for the purpos

room. The ory-acceptene torch is used for the purpless, the intensity hot finne cutting off the steel amost like butter at the exact elevation desired.

The hollow shell is next filled with concrete reinforced by means of long two-inch steel rods, semestines fifty feet in length. On clusters of these concrete-dilied plies, the weight of the building is supported.

That this method of constructing foundations is in-

deed rapid, the story of the wark at 145-147 West Twenty-eighth Street, New York city, proves. Rock was located 38 feet below the curb. The material above it

the car are when the was still ten days of Torond the only solution were drawn which and steel plies, driven is read, and stied with constit, and stied with constit, and air, and Stied with rods. Despite various ing of neighboring to was started on June taking out his run foundation bad been o expected arrival of the study.
Such rapid work is not unusual
tion method. On another contra

tion method. On another contract, not in the three menths significant month and a helf, during which be vation had been done, including all driving, the mounting of charges wall, and capping of the piles swally

Sometimes difficulties are emocrated prove all but insurmountable and certification expensive with other methods.

expensive with other mentions. The street from the curb. Two reaching intersected at that point. The piles were sunk through the stream to ro any difficulty.

The excessive cost of open pit work has some-times made it impossible to build twelve or fear-teen-story buildings in many sections of the city of New York. The steel pile has, hou steel building construction profitable.

The carrying capacity of a steel pile is ener-mous. On a single 12-inch steel pile one hunmous. On a single lateness used page on aundred tons can be safely maintained. Piers containing sixteen piles have been sued, and leadings up to 1,300 tons are not unusual.

Naturally the question arises: Do the steel

piles deferiorate in time? The question has been answered over and over again by the piles themselves. After a service of fifteen pairs the steel foundation piles were remained from the site of a building which now minute at the northwest corner of Wall and Resents streets, in York city. They showed practically no de-ration. The oxidation on the outside was al-

#### New York's New Fire Alarm Box System

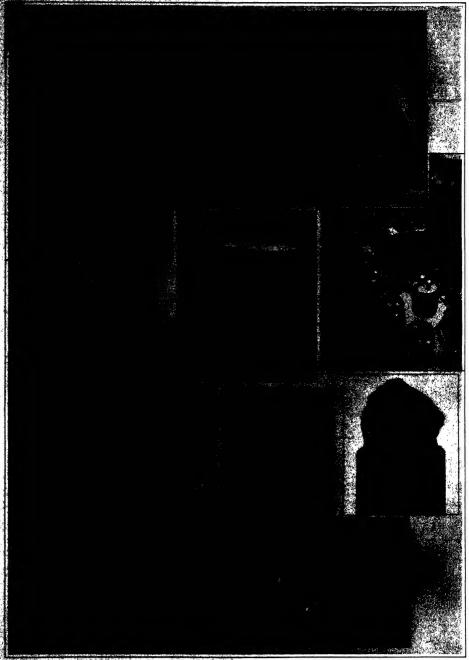

FTER work extending over two years. Mr. A Leonard Day, chief of the Fire Alarm Tele-graph Bureau, and Mr. E. A. Failer, telegraph expert of the Fire Department, have devised a fire alarm box which has been dedicated to the fire alarm box which has been dedicated to the use of New York city without royalty, and it is expected that the cost under competitive bidding, will not exceed \$48. The price of its alarm boxes during the past several years under competitive bidding has run from \$70 to \$875 oct. The average price has been \$129 each. The average price has been \$129 each. The settlanted saving, therefore, will be \$80 per box. The Fire Department experts have distinctly, as only six per cent of the boxes are modern, the rest being obsolete, and many being in an unsets and

even dengerons condition.

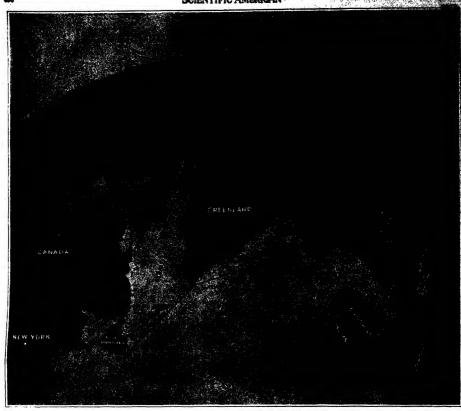

In view of the fact that the new Fire Alarm Telegraph system, including the holated central stations, cables said connections will require the installation of fitteen thousand new bosie in the next five years, it is estimated that the saving to the offy through the weigh which has just been completed will be in round numbers

Map of the North Atlantic Ocean, showing the points for way stations and distances in an aerial relay flight to Europe.

## Way Stations for a Relay Flight to Europe

How the Atlantic Could Be Most Easily Crossed in an Aeroplane

By Henry Harrison Suplee

W 110 can doubt that within a comparatively short time one or more buman beings will have traveled from America to Europe, or the reverse, through the air? Whether this journey is first to be made in a machine which he lighter or heavier than the air through which if moves, does not yet appear, and it seems as if this point depends more upon the mant than upon the machine. The remarkable trip from Parls to Warsaw and return, by Brindelone dee Moullands, was made in an acropiane, while the latest Zeppellin model is specified to have the adulty to remain in the air for three days, and to have a speed of sixty miles an hour. Either machine should be rendered capable of making the attiven hundred miles between Newfoundland and Ireland within a period estimated at from thirty to forty isours.

The elements of difficulty in the undertaking arecomparatively few in number, and of a nature equibit of critical investigation and solution on land, with one or two exceptions, always assuming that sufficient funds are available. For the accopiane the most important thing is the assurance of the reliability of the anotive power, for the diricible it is probably the multitenance of the lightness of the envelope, and the consequent assurance of the ability of the methine to remain in the air for a long enough time. For both machines, however, the human element

For both machines, however, the human element forms one of the indeterminate features; the other one being the possibility of being carried far out of the way by reason of fog and by air currents. Assuming that the problem of motive power for the acropiane is empirior as incution either by improvements in the design of the earlie and extreme ever in its construction, or by the depileration of the motive power machinery is such a manner that the navigation may shift immediately from one engine to the other; and accepting what is sirvedy believed to have been accomplished with regard to the length of time which a dirictible can be maintained affont, we come to the two indeterminate features already mentioned. There is no doubt that the necessary erwe could remain comparison of the control of th

If we turn for a moment to other and far more highly developed machines for transportation, we find that not thought is given to the imposition of any such strain upon the operator, and that it is assumed without question that both machine and man have very definite limitations. High-speed railway trains change both expine and driver every three or four hundred miles, while on occass steamers, where the motive power cannot be relieved, a sufficient number of men is provided to divide the labor igto watches giving ample opportunity for rest and recuperation.

With but few exceptions, those who have discussed

the problem of crossing the Atlantic through the air have feit themselves bound by the precedent of the atennable, and assumed that a continuous and uninterrupted voyage is a necessity. It has aircard been pointed out, however, that it is entirely practicable so to divide the trip as to bring its various portions well within limits of endurance aircard readily sustained both by the man and the matchine.

If we take the attempt as being made from America to Surope, and examine the possibility of molityriding the trip, regardless of thesianes followed by the existing stemminly lines, it is evident that a start from Newfoundard, passing by way of Greenland, Iennal, Farne Jakada, and Norway, would give opportunity for the division of the vorage into four sections, of not greatly differing lengths. Following the presedent of railway practice, and lotting seek section be traversed by mon and machines in reiny, it would not seem impossible practice, and long, for example, to Europic through the send a mail larg, for example, to Europic through the alt, with the apparatus which is even sow; at our disposal. When this has, been successfully accomplished it will be time enough to think about existing out one more of the way stations. This would desaut in the employment of an entire the start was sinch, and in the employment of an entire very operators. Dioblides seem which regards the undertaking in the same light as a neithed would—not appeal in the employment of an interior throat the same light as a neither would—not appeal in the same light as a yeach raw or similar event; but when considered whichly spectures or similar event; but when considered whethy

as a conservative engineering problem, the plan may well be examined upon its merits.

Farewell, Greenland, is a distance of nine hundred and forty miles, this being the longest leg of the trip, and one which might be very materially shortened if a satisfactory starting place could be assured on the coast of Labrador. From Cape Farewell to Reikjavik, Iceland, is somewhat shorter, being eight hundred and twenty miles. These two portions of and twenty miles These two portions of the voyage, the first traversing Davis Strait and the second crossing Denmark Strait, are those in which the difficulties of for are most ant to be encountered although it is possible that the route may pass farther north than the region of enue for.

From Reikjavik to the Furoes is fo hundred and sixty miles, and from the latter it is four hundred and twenty miles ergen, Norway.

This makes a journey of twenty-six hun-dred and forty miles, divided into four fairly equal stages, permitting the diffifairly equal stages, permitting the dim-cuities of endurance, both of man and machine, to be reduced in far greater pro-portion, and bringing the question of fuel supply into altogether managorable shape. It may be said that such a route is allo-gether undesdrable because it begins and and at wholly makes undips and follows.

gether undestrable because it begins an ends at wholly useless points, and follow unsultable places on route. The greathing, however, at present, is to demon strate the possibility of making the cross-ing at all, and this once accomplished, it is probable that important modifications would follow

In any case it must be remembered that it is irade routes which create their own desirability. When all commerce with the Orient was conducted from Venice and Genoa eastward, the commercial import-ance of England was little greater than that of Iceland, and it was the sudden change in the face of Europe, after the new routes to India and America were opened, which placed the British Islands in the front of the commerce of the world. facilities create traffic in all parts of the globe, and when the routes are established they can be depended upon to bring many changes in their train.

In the meantime it may be desirable to sessitate before demanding from the aeroplane and its operator feats of endurance hich have never yet been asked of the locomotive engine or its driver, and be well satisfied that the North Atlantic is apable of division into practicable sec tions for serial payiontic

#### Fighting with Dynamite and Electricity

(Concluded from page 488.)

the enemy. When the grenade is to b fired, an electric current is sent through the cable, whereupon the grenade is projected upward to a predetermined h (generally three fe et), where it explode and simultaneously discharges the four hundred projectiles in a horizontal direction, radially from the center, and parallel to the surface of the ground so as to sweep ihis in its entirety over an area of at least square yards

At a distance of 40 feet the projectile will pierce a timber wall at least 4 inches thick, exerting mortal effects up to 96 Hence this grenade partakes of the properties of the underground mine, explosive shell and shrapnel shell.

At the same time however it offers a number of conspicuous advantages. Since number of conspicuo both the grenade and the cable are buried entirely in the ground, the mine field is hidden so completely as to make detection by the enemy altogether impossible. Moreover, the grenade, thanks to its special design, will always explode exactly at the height most advantageous for the explosive effects Again, it invariably explodes with its longitudinal axis perpendicular to the ground, its four hundred projectiles being thrown out in all directions, parallel to the ground, so as always to insure maximum shooting effects.

Way Stations for a Relay Flight
to Europe
(Concluded from neer Add.)

(Concluded from neer Add.) n during transport mature explor and while being handled and installed. It may even be fired on with ride balls at short range, without being caused to ex-plode. The fuse can mirrover be removed and inserted at any moment.

and inserted at any moment.

Assen grenades are inserted into holes dug in the ground with the spade or yield or with a special drill. In underspining a road, the shells may be arranged along-side the wayside, 20 to 25 yards spart, when the constitution will researched. Instead of connecting up all grenades a given field in series and exploding the simultaneously, they may be arranged in several series, thus allowing a given mine sheld to be fired in several sections. The shells may also be provided in duplicate or in triplicate, so that after firing the first set, the fuses have only to be connected up to the next set of electric cables, to order again to establish the mire field.

Grenades once planted may remain in

the ground for years without suffering any damage. If the mine field be tilled ground, it may even be used for agricul-tural purposes without incurring any

#### The Great World Wireless Circuit (Concluded from page 488.)

Suitable flanges permit the sections to be bolted together, end to end. Further, the ten-foot sections are themselves made up of two parts which are also bolted to or two parts which are also notice to-gether, vertical flanges being provided for the purpose. The boilting up is done when the individual pieces are placed in final position. That is, the towers are erected piece by piece. Some of the secti at other locations are higher than ten fee and have larger diameters than those and have larger diameters than those at Belmar. Sections of large diameter are sometimes made up of four quadrant pieces provided with vertical flanges. The pseces province usin vertical flanges. The metal is comparatively thin, the parts be-ing made of sheets pressed to shape, each piece flanges and all being absolutely with-out seam or joint. At least, this is the type of steel work being used in New

The lower portion of a tower has The lower portion of a tower has a larger diameter than the upper, a tapered latermediate section being used to connect the two halves. At the very top, a wooden mast projects from the hollow steel. This mast carries the supporting arms, which in turn bear the weight and strain of the acrisis. It is used as a help in construction from the time the work reaches the halsth of twenty or thirty feet. From height of twenty or thirty feet. From this point on, it is hoisted up step by step this point on, it is noiseed up step by step of as the construction advances; it is always to be seen projecting above the top of the steel work. The manner of holsting it up from time to time is very interesting. A steel rope is temporarily attached to the appermost horizontal flange of the unfin-ished lower, or runs over a sheave tem-porarily fixed at this point. In the latter case, the rope is carried down to son venient point and secured. From the top of the tower, the rope passes down inside to the bottom of the wooden must when it passes round a sheave and up the oppoit plasses round a sheave and up the eppo-site side to the top of the tower again Hero it passes over a sheave and down the outside to a point near the ground where another sheave permits its direction to be changed to the horisontal. A hoist ing engine winds in the horizontal section and thus effects a raising of the wooder must: When the mast has been lifted the height of a single tubular section, a bar is passed through both steel and wood is passed through both steel and wood At overy one of its positions, the mast pro-vides support by means of four radial arms for the raising and lowering of a kind of movable beloup. The helicopy is moved up and down by the workmen on it, who operate the bjock-and-tockle arrange-ments which connect radial arms and balcony. Standing on the belony, the usen are able to do the hoisting and

seen and now to up any nomining my ing of wheel please and also the hold them in final position.

The towers stand on heavy so foundations, but are not sufficiently founds time, but are not enforcedly strong to maintain rigid positions without or, parall auditation. This is provided by (Countain on page 281)

S PRINGS — good springs — contribute more to your motoring conflort than you have thought. They for the foundation of the smooth gilding movement of your car. Beep highbetry and resilient power of the smooth gilding movement of responsibility is out the springs. Give Dentoil Springs ther speculation, Give Dentoil Springs ther sproposal for you and for the car mechanism. And they're safe. You can trust them in any more greatly, though the state of the springs of the s

You want to know what carburetor your car has what tires—the power of the engine. Demand, too, the springs you want — Detroit Springs.

#### Specify the Springs that are "unhurriedly made"

There are factory reasons for every good quality you notice in Detroit Byrings. When you specify Detroit Springs you're specifying the workmanship of the past may be a factor for the past when you was a factor for the past may be work by won't let them rush a single one of the forty-eight processes.

## In Detroit Springs You Specify Also Springs That Won't Squeak

— Springs that lubricate them is during automatically. You specify springs that have stood up under three decisive texts: the "Initial Text," the "Hardness Text," the "Capacity Text." These tests prove in advance what you should know, that Detroit Springs are restlient, strong, equal to every possible shall-load strain. These tests justify us in gamanteets justify us in gus toeing Detroit Springs

toeing Detroit Springs for two years.

Free..."From Ore to Motor-Car," our spring book, which gives the reasons why you should not be estisfied with less than Detroit Springs.

Writes for it now.

Detroit

means of an elaborate system of steal guy repass secured to the towers on four sides and at various heights. At their outer and at various heights. At their outer bleeks buried in the syrth. It was thought that fong seel guy ropes might whate closely energh in union with the wireless to set up an interference. Conse quantly, the guy ropes have been broken up into harmiess lengths. Where two lengths have to be joined, this is accomlengths have to be joined, this is accom-plished in such a way as to eliminate actual contact of rope with rope. Loops on either end pass through each other, but have in-terposed between them heavy pieces of percelain. The blocks of porcelain are thus put under compressive atress which they are well able to endure, but are not permitted to undergo tension. Both at Belmar and at New Brunswick, the columned of themse are now with

Both at Belmar and at New Brunswick, the columnades of towars are one mile long; there is, however, a double colou-nade at the latter point because of the number of aerials requiring support. At Belmar are to be housed a consider-able company of operators and the like. The company is putting up its own build-ings for this purpose as well as for the more immediate necessities of the reception and transmission of messages. The a one-way station operating by long dis-tance wireless with Wales only. At Hono-iuln, a two-way station is being construct-ed which will connect with San Francisco on the one hand and with Yokohams (or possibly Hong Kong) on the other.

#### Making Colored Photographic Reproductions With the Aid of Blue Prints

JOHN LEWISCHN of New York has invented a method of making colored photographic reproductions, in which the blue coloration in a blue-print is utilized as one of the primary colors.

A negative of a colored object is made

on an ordinary orthochromatic photo-graphic plate, using a yellow colored screen, in order to obtain the best color values. From such a negative, an ordi-nary blue-print is made, which blueprint will, of course, show up the differ-ent shade values in their proper propor-tions. This blue-print is then colored either wholly or in part, by applying red eosin and aurantia, or a mixture of the two, to modify the blue to form any of the spectrum colors, the blue coloration showspectrum colors, the blue coloration snow-ing through the applied washes with more or less intensity depending upon the ex-tent of the coating wash. Should it be desired to make all or any material portion of the print either red or yellow, or any other color, in which blue is not used, the blue of the blue-print is either wholly or partially dissolved by a weak solution of nitrate of sliver, which will fix the colors, and, at the same time, will gradually bleach out the blue. Further, the blueprint may be washed with this solution, if it is desired merely to weaken the blue it is desired merely to weaken the bitue color of the object, after the codm or surantia has been applied, or a mixture of the two, to form any of the spectrum col-ors involved in these two primary colors should it be desired to restore the blue locally or entirely, or to darken the blue

#### Do You Remember When This Fivent Occurred?

It was a long, long time ago.

So long ago that most people who were alive then have forgotten it. And yet it was great news then,

Sitting Bull had surrendered!

Such a scene can never occur again. Mr. Indian of blanket and hunting for scalps, clothes himself in fashionable attire and goes in for athletic honors.

That is only one of the great changes that have taken place in our country since Richmond Straight Cut Cigarettes first won their immense popularity – 42 years ago. During this time, Automobiles, Electric Lights, Telephones, and many other improvements have become a necessary part of our everyday life.

But through all this period of change Richmond Straight Cuts have stood supreme, the best of all Virginia Cigarettes. They cannot be improved upon.

A BOOK of engineering for boys, telling in a boy's own way what every boy wants to know. It recounts the experience of two young lads who spend a summer vacation seeing the engineering wonders of New York. The boy with red blood in his veins will be thilled by the numerous adventures, all based on fact, showing courage, presence of mind, loyally to comrades and devotion to duty, at the same time he will learn how the big things of engineering are being done. A dozen engineers, experts in their several lines, have read and revised the manuscript.
